The postdoctoral position is a valuable means to acquire specialized skills and gain more competence in addressing key problems

Fundamental issues and challenges

1) Remuneration: It is commendable that NIH has stipulated a minimum salary for a postdoc. PIs are compelled to keep to that minimum but it is barely adequate given the present economic realities and family responsibilities (e.g childcare).
2) Workload: Most quarters often use postdocs as cheap labor. Working over time seems to be the norm. The pressure to generate data and publish does not consider the health of the personnel. Adequate remuneration may compensate for this.
3) Competitive industry packages: the recruitment and retention of postdocs is dwindling because there are increasing number of attractive positions outside of academia and the slim possibility of securing faculty positions make many look away from taking a postdoctoral position.

Existing NIH policies, programs, or resources

Career Development Awards should be increased

The minimum salary should be adjusted to reflect current economic realities, which can be addressed directly by removing modular budgets for R01 upwards

Proven or promising external resources or approaches

Enhancing postdoctoral welfare enhances science quality and postdocs satisfaction

Response 1113

Perspectives on the postdoc roles and responsibilities

Kate Saylor's comment on the RFI announcement reflects my feelings identically in response to this question.

Fundamental issues and challenges

I've already made up my mind to leave my post-doc position before the end of my first year because I know that my skills, expertise, and overall work ethic will be better valued and compensated elsewhere--not to mention the guarantee of better health care, paid parental leave, greater job security, and more opportunities to work from home.

Moving through the U.S. educational system without generational wealth as a safety net is brutally difficult. Students are forced to accrue massive amounts of debt all the while being faced every day with homophobia, sexism, and racism (and more) because the people who succeeded in this system before are untouchable and, simultaneously, the ones deciding our futures. An anonymous commenter on the RFI announcement put it well: ".many graduate students do not receive a stipend, and even for those who do, it is hard to save money. Therefore, there is added pressure on post-docs to begin to start saving as soon as we leave graduate schools.We made the decision to trade years of earning salary for years of education when we went to graduate school."

The current system functions by baiting PhDs into working insane hours for too low of pay and poor job security with the flimsy promise of something better in the future. People used to stick it out because they were passionate about changing the world. But industry and non-profits get evidence-based practices to the people who need them the most far quicker, and that work is respected and appreciated. With more PhDs leaving academia, there is excellent research being done elsewhere, and a post-doc position is no longer needed to develop one's skills enough to be capable of a successful career.

We are already valuable, but we are treated as though we are not.

Existing NIH policies, programs, or resources

NIH-funded academia is falling woefully behind all other sectors not only in pay, but in recognizing and correcting for the ways it reproduces inequality (see Alan Attie and Aina Pruce's comments on the RFI announcement regarding the treatment of non-U.S.-citizens by NIH policy as just SOME examples of the ways in which NIH reproduces inequity and hinders the creation of a diverse science.

The questions to be asked here are —Why were we not set up to detect this issue before it arrived? Who has a seat at the table, and who have we silenced or ignored? Why was incremental change made when sweeping changes were called for? Why were we not a space that felt inviting to diverse voices or to individuals hurt by this system and willing to share their experiences?

Proven or promising external resources or approaches

Increasing pay for employees is proven to improve work climate. Providing health insurance (so many post-docs fall through the cracks, not quite students and not quite employees) is also likely to reduce turnover. The NIH has received EXCELLENT recommendations already in the comment section of the RFI announcement. I recommend using a qualitative analysis to identify common themes in the suggestions made by individuals with lived experience in the system you're seeking to change. Yes, you can look elsewhere. But the answers have been placed at your feet with many of the same answers stated over and over again.

Response 1114

Perspectives on the postdoc roles and responsibilities

The role of my postdoctoral position is to carry out the general vision of my lab. I collaborate with colleagues to execute cutting-edge experiments and develop new technology and software that aid the research community. My responsibilities include managing day-to-day experimental workflows by doing

the experiments, delineating general experiments to staff, and interpreting results to ensure the research direction is progressing. In addition, I'm deeply involved in my lab's grant development (e.g., RO1, etc.) while developing my own independent grant (K99).

Fundamental issues and challenges

I'm optimistic about academic research. I genuinely believe it to be the best platform for scientific creativity. However, the majority of my postdoc colleagues are growing increasingly concerned about their long-term job potential while managing short-term financial shortcomings. Some colleagues, who are the primary caregivers of their family, understandably opt for more lucrative financial positions outside academia. As a postdoc myself, I'm constantly approached by industrial recruiters who offer me two-times my current salary. I turn them down because I consider academia the only way I can fully carry out my scientific goals.

Existing NIH policies, programs, or resources

The general academic environment appears to be, at times, overwhelmingly concerned with financial stability. The pursuit of stability influences the science, and the science eventually becomes risk averse. Inevitably, lab morale becomes unbearable for many lab members. Who wants to be work in a low-morale environment? Especially ones that inherently don't offer comparably lower incentives?

I don't confidently believe that I have answers to improving research career pathways. I tend to believe, though, that increasing the modular budgets per R01 has potential—or rather, more money per grant. I was surprised when I found out that the $250,000 modular budget has not increased in nearly 25 years, despite inflation and the need to integrate greater resources to address a scientific question (e.g., computational power, omics, etc.).

The majority of PI's and colleagues with whom I collaborate are consistently writing R01's despite having already secured funding. "It's not enough," I'm told.

Proven or promising external resources or approaches

I believe the NIH has a more indirect rather than direct influence over the training and working environment of the lab. Rather than spreading out its funding in multiple RFAs, tighten funding by investing more on a per-grant basis. This might mean sacrificing certain RFAs.

I understand this isn't an easy or even practical solution. Simply increasing RO1 modular budgets would create problems: it could decrease overall RFAs, increase competition for what would be fewer grants, and disparage some labs. I'm hoping that those closely involved in this process consider ways to stabilize the long-term picture of some labs, so that the environment morale increases and more money can be dispersed to the employees themselves rather than equipment and resources.

Overall, the NIH can enhance postdoctoral training by doubling-down on what it's so close to offering: near full-autonomous creativity and control on long-term projects with enormous societal impact. Constantly writing five-year grants for modular budgets that haven't increased for a quarter century gets in the way. Rather than focusing on long-term projects, postdocs (and PIs) are focused on short-term funding that ultimately affects the quality of their research, quality of their lives, and quality of their colleague's lives. Industrial positions offer greater long-term security by paying more up-front. In its current form, academia can't financially compete with the boom of industrial health research.

Response 1115

Perspectives on the postdoc roles and responsibilities

My opinion is that the role of the postdoc is to carry out their own projects under the guidance of a principal investigator (PI) and also contribute to research projects developed and funded by the PI's grants. This can and should also involve the supervision of graduate and undergraduate students. The overarching goal of a postdoctoral researcher should be to develop their own research program, gain practice and experience in mentorship, and to develop the necessary skills to become an independent investigator.

Fundamental issues and challenges

Recruitment of postdocs is inhibited by several factors. Newly-minted Ph.D.s who want to become University professors are discouraged by the low probability of actually attaining that goal. Many of them

have seen highly skilled and very successful postdocs spend countless hours on applications that ultimately go nowhere. Postdocs on the job market see that there is often a select group of candidates that receive multiple offers, sometimes leading to failed searches. There are many postdocs who would be great and succeed in the position where the search failed, but there are few options for offering these positions to candidates that did not make it to the initial interview list. They also see that existing assistant professors also apply for and are interviewed for these jobs and many open positions are filled by existing assistant professors that want to change institutions. This makes the actually supply of assistant professor jobs even lower for candidates at the postdoctoral level. Other newly-minted Ph.D.s see the life of a professor and decide it's not for them, due to the high demands and lack of work-life balance. Options outside of academia are seen as more desirable for their overall life goals and a postdoctoral position is not required for these jobs. For these new Ph.Ds, it doesn't make sense to spend a few years in a postdoctoral position at a lower salary. If a postdoc is not needed, then it makes more sense to directly start a job that is on their career path.

Existing NIH policies, programs, or resources

I think that the NIH could offer programs that provide a fellowship for a joint industry—academic postdoc. Current postdoctoral fellowship programs could be improved by offering better support for university job applications. Or perhaps, a program where a current or former NIH postdoctoral fellow could send the NIH the research statement that they are using for job applications as a type of grant application where the NIH would promise to award the candidate a specified sum of money to support the candidate's research program if they end up securing an assistant professor position. Ideally, this would happen in advance of the actual job applications and the Universities would know that these candidates would have additional funds from the NIH and that would provide the candidate a better chance of getting hired.

Proven or promising external resources or approaches

Ultimately, I think that the solution might be to offer better incentives for doing a postdoc in the first place. This might involve a shift away from viewing postdocs solely as trainees and offering real career-level positions for them within academia. This would mean real pay and real benefits and some degree of job security. I am not sure that there is much that the NIH can do about this other than to increase the pay scale and that would also have to require increasing the budget. I understand that it is incredibly hard to get Congress to increase the NIH budget, but perhaps the NIH could invest more effort into engaging with our congressional representatives to show them the value of basic research and request the funds necessary to keep the US a powerhouse of science and innovation.

Response 1116

Perspectives on the postdoc roles and responsibilities

Mentored but semi independent research to improve skills and experience to one day lead a research group

Fundamental issues and challenges

Salary and benefits are really low. The lack of retirement matching or other common employment benefits is very worrisome. Mentorship access is very unequal, and mostly doesn't make up for poor payment. Specially compared to industry. We are treated like employees without proper and clear guidelines for vacation time, time off and sick leave, but paid as trainees? And that is not even in cases with abusive dynamics from labs especially for international students that depend on visa sponsorship

Existing NIH policies, programs, or resources

If postdoc is a training stage, then make sure training is given. If postdoc is employment as researcher, adjust salary, benefits and expectations/working hours and goals to a job like position. Also, make international postdocs eligible for Grant's or other sources of funding to reduce our vulnerability to PIs due to Visa and funding issues

Proven or promising external resources or approaches

Harvard medical school postdoc surveys and suggestions recently published

Response 1117

Perspectives on the postdoc roles and responsibilities

Lead research and build skills to land a permanent professor/research job.

Fundamental issues and challenges

Pay sucks! Hours are long. Having to move around every 3 years when trying to start a family is terrible. Impossible to save to buy a home

Existing NIH policies, programs, or resources

Raise the salaries to $100k+

Proven or promising external resources or approaches

No response

Response 1118

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

Postdocs are not paid enough to live. When you live paycheck to paycheck, as so many do at my institution ([redacted for anonymity]), life is not secure and quality of life is poor. Accidents or events that may be considered "small issues" to those with financial security, can be severely damaging to those without financial security. When qualify of life is poor, this leads to difficulty in retaining postdocs and in recruiting new ones. All three of these issues could be substantially improved by paying postdocs a living wage.

Existing NIH policies, programs, or resources

No singular training or policy can fix systemic issues in recruiting and retaining postdocs. The solution must be an increase in pay for postdocs. With greater financial stability, graduate students may be more willing to take a chance on a postdoc than settle for the comfort of industry. Postdocs are highly skilled doctors —they should be paid a living wage.

Proven or promising external resources or approaches

No response

Response 1119

Perspectives on the postdoc roles and responsibilities

The postdoctoral researcher job is, currently, both

1. a necessary step in the current academic system, needed as a buffer between the large pool of PhD students wanting to work in public research and the small number of permanent academic positions that open every year and
2. the only position in the academic system of many countries, including the USA, where one can fully devote their time to research without wasting time on distractions like teaching, going to classes, learning how to do research, doing paperwork or admin, etc.

Fundamental issues and challenges

This question is poorly worded, the problem is not how to recruit more people as postdoctoral researchers but how to *instead* recruit more people in permanent positions of interest without spending unnecessary time in unstable, short-term positions where the individual is at the mercy of the PI.

Existing NIH policies, programs, or resources

Fund positions of "permanent scientists" (no admin, no teaching).

Proven or promising external resources or approaches

No response

Response 1120

Perspectives on the postdoc roles and responsibilities

Aside from my own scientific research, I oversee/train graduate students, write grants, and come up with new project ideas.

Fundamental issues and challenges

There is no salary adjustment for universities in a high cost of living city. With inflation, it is not feasible to do a postdoc after a PhD student salary. Additionally, the postdoc appointment timing is during prime child bearing years. The pay does not support having a child and the 8 week maternity leave is too short. Recovery after having a child is challenging and some people are just starting to walk after 8 weeks let alone conduct rigorous scientific research. The $2,500 child care supplement is only one month of daycare in high cost of living cities. Thus, unfortunately, you will see less and less women participate in postdocs.

Existing NIH policies, programs, or resources

Increasing the child care stipend to at least $5,000. Increasing maternity leave to at least 16 weeks. Increasing salary. Providing child care and cost of living adjustments.

Proven or promising external resources or approaches

Honestly, it's about the money and benefits. That is the only way.

Response 1121

Perspectives on the postdoc roles and responsibilities

- Completing research projects and publishing under short time constraints due to career expectations.
- Taking on administrative responsibilities in the lab, in many cases serving as a proxy principal investigator in the lab.
- Mentoring students and technicians.
- Serving as an overflow labor resource for other projects in the lab that are understaffed due to turnover or poor project management. This may include experiments, grant-writing, and last-minute presentation preparation.

Fundamental issues and challenges

After receiving my PhD I was dissuaded from postdoctoral research for a number of reasons:

- Postdoctoral "trainees" are under-compensated for their role, which has been traditionally justified by categorizing them as trainees instead of professionals with years of expertise. Pursuing this path can cost individuals tens to hundreds of thousands of dollars over their lifetime when compared to nonacademic career choices (https://www.science.org/content/article/price-doing-postdoc).
- Postdoctoral positions are part of a bottleneck to scarce, highly coveted positions as professors or principal investigators. During my PhD, post-doctoral candidates were under constant pressure to complete their projects quickly, sacrificing their own work-life balance with little promise of job security.
- Postdoctoral professionals are often expected to build and develop novel projects, but they may or may not be able to take those projects to subsequent positions, further restricting their career progression.
- Many principal investigators lack formal mentorship training, forcing postdoctoral professionals to manage-up or serve as managers for their lab.
- Postdoctoral professionals may be held back from publishing by their principal investigator who want more, or more impactful, experiments. I have seen postdoctoral professionals held back for months or years, which has substantial impact on their career path (and lifetime income).
- Career support and mental health resources are often lacking for postdoctoral professionals. They often have little protection from unhealthy power dynamics at their institution.
- High pressure work environments and lack of support contribute to poor mental health, including high rates of anxiety, in postdoctoral professionals (https://www.semanticscholar.org/paper/Flourishing%2C-Languishing%2C-and-Depressed-Fellows%3A-in-Gloria-Steinhardt/8108007d751855d62077a1a15d8ab25c9bb86323).

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1122

Perspectives on the postdoc roles and responsibilities

A training position primarily for a later faculty position

Fundamental issues and challenges

while the salary is sufficient for postdocs without children, it is insufficient for those with young children

Existing NIH policies, programs, or resources

NIH resources, policies, and programs should not be biased in favor of postdocs from certain backgrounds. The current system to support underprivileged postdocs is unfair to the other groups and will in fact hurt those groups that NIH intends to support.

Proven or promising external resources or approaches

Please reduce such bureaucracy

Response 1123

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

Industry was booming and postdoc positions in academia are exploitative. At least for a HCOL area like Boston, postdocs are paid 25% under the living wage for one person living as part of a 2 person family. That cost goes up for singles living alone and up A LOT for people with any kids. The salary is "insulting" for the level of skill and even societal contribution; it's not just that the pay is a bit low. It's completely scandalous. Genentech pays their post docs $86K plus bonus, 401K match and stock options.

Existing NIH policies, programs, or resources

42 U.S. Code Â§ 288(b)(5). More money for post docs

Proven or promising external resources or approaches

10.1038/s41587-023-01656-4 A Nature biotechnology article about retaining post docs

Response 1124

Perspectives on the postdoc roles and responsibilities

I viewed postdoc positions as additional time working with faculty in my field that was needed to publish in an effort to land a tenure track job. However, in my field I kept seeing people spend 6+ years in a PhD program followed by two or three postdoc positions in order to potentially be hired as TT faculty. That's too many years at such a small salary.

Fundamental issues and challenges

Salary. In my first year of an industry position I was paid triple the salary of a postdoc. Plus, my industry position is 40 hours a week.

Existing NIH policies, programs, or resources

Postdoc salaries need to increase. Faculty need treat postdocs as professionals and not glorified research assistants.

Proven or promising external resources or approaches

Again, salary. Can academia compete with industry in terms of salary. Of course not. However, the salary gap has widened. The chances of obtaining a TT job is too small.

Response 1125

Perspectives on the postdoc roles and responsibilities

Postdocs are highly unprotected, unregulated and seen as cheap labor

Fundamental issues and challenges

Switching labs from toxic bosses means unsupported labor and going without pay for possible months. In addition, it also means a loss of health and dental insurance. Because of this, I have to work outside jobs to make ends meet, which distracts me from the science itself. In addition, because my postdoc research is tied with my loan repayment funding, in between this switch, my LRP did not pay for my loans. As result I received a deliquency mark on my credit score which made it dropped 56 points. Working a postdoc has not only mean I have to still struggle financially but it negatively affects my mental and emotional health to the point where I regret applying for the award and dong a postdoc. I can't even go to the doctor for counseling or for any other reason (in a pandemic) because of this. I am literally in hell.

Existing NIH policies, programs, or resources

Higher pay, guaranteed gap funding and health and dental insurance in the case of potentially switching labs. Not having the process of transferring grants take months. Not using the reimbursement model and allowing postdocs to have access to discounted child care

Proven or promising external resources or approaches

Higher pay, guaranteed gap funding and health and dental insurance in the case of potentially switching labs. Not having the process of transferring grants take months. Not using the reimbursement model and allowing postdocs to have access to discounted child care

Response 1126

Perspectives on the postdoc roles and responsibilities

- I view the post-doc position as one that is too narrowly focused without sufficient breadth to allow for the pursuit of individual research initiatives and not just conform or fit in with current initiatives. I may be wrong, however.
- I view research studies, including those of NIH, at risk of not considering/testing implicit bias as a confounding variable in trials. It could account for disparate outcomes between/among races. We won't "know" unless it is tested. It won't be tested unless included in the research design. It won't be included in the design unless NIH directs its inclusion.
- The study of racial bias among research investigators, staff, post-docs, research personal needs to be studied by each Institute as any other confounding variable and not simply delegated to the Institute on Minority Health and Disparities.

Existing NIH policies, programs, or resourcesthat could be modified, expanded, or improved to enhance the postdoctoral training ecosystem and academic research career pathways.

- See above suggestions. If I, a White, can identify problems within NIH research, just think how much more POC could identify, if they were included as post-doc investigators and encouraged to critically analyze research designs.
- Proven or promising external resources or approaches that could inform NIH's efforts to enhance the postdoctoral training ecosystem (e.g., improving postdoctoral recruitment, training, working environment, mentoring, job satisfaction).
- Include NIH's commitment to decrease implicit bias as a confounding variable in research design. This alone will
- increase recruitment (I bet on it).

Fundamental issues and challenges

See the above. It is not just the post-doc program that needs improvement, nor is it just NIH, but all research institutions. But, NIH can again lead the way. DEI are not just concepts, goals, etc. DEI are the lifeblood of institutions that claim to study objectively, scientifically asthma, infections, HTN, diabetes, nursing, mental health, arthritis, clinical services, scientific review and more.

Existing NIH policies, programs, or resources

See above —Thank you for this opportunity. It is a great start. [redacted for anonymity]

Proven or promising external resources or approaches

See the above.

Response 1127

Perspectives on the postdoc roles and responsibilities

I view the postdoctoral stage as the period where a scientist transitions between the training-focused position as PhD Student and the position as an independent scientist. THus, this stage should focus on the skills required for becoming an independent scientist, for example leadership and independence skills. It should include training of younger scientists, managing projects from a more senior position, establishing collaborations and other leadership activities.

Fundamental issues and challenges

For me a clear issue is the salary. The average age for a postdoc is around 30 years old and a long trajectory of high-level education and usually more than 5 years of employment in science (research assistant, PhD student.). However, the salary is not clear in accordance with these qualifications. Why has the academic postdoc job has to be paid much worse than any other job that you can get with that education/CV? Solving that will really help with recruitment and quality of life. It is really difficult to think for example of forming a family (which usually starts at that age) with that low salary.

Salary will help retention too but there are other pressing issues here regarding retention, and that is the low number of senior positions in academia. We all know it is so difficult and competitive to start into the tenure track, but there are no real alternatives to continue after postdoc in academia. There should be a focus on that.

In my view, there is also no accountability for the role of the supervisors/mentors in the progression of academic career of their trainees, thus leading to so many cases of abuse that I am sure cause many people to quit and find some less-stressing job that does not break your mental health.

Existing NIH policies, programs, or resources

K99 is a great program but the success rate is so low that an increase in funding would really help to enhance the postdoctoral training ecosystem.

Proven or promising external resources or approaches

In Denmark there is a compulsory annual meeting about career development that leads to an official document in which both mentor and mentee commit to different objectives.

In some fellowship programs, it is also included a full workshop on career development, which is really helpful.

Response 1128

Perspectives on the postdoc roles and responsibilities

What the post doc SHOULD be is training to be academic faculty. This means that the number of positions should be proportional to the number of likely academic roles, so we have too many PostDocs.

What the post doc WINDS UP being is cheap PhD level labor for NIH grants. This is not a hard problem, it’s about money. PostDocs are woefully underpaid for what they bring to the table. The NIH and universities together need to identify how to have compelling jobs for Associate Research Scientists and then structure grant funding so these people can be paid appropriately.

If the NIH intends to raise PostDoc salaries, which to me seems like a necessary first step, there needs to be mechanisms developed to help support increase in pay.

Fundamental issues and challenges

Low Pay

Moving for a short term contract

Low prospects for continued academic success

Existing NIH policies, programs, or resources

Response 1129

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

No response

Existing NIH policies, programs, or resources

1) NRSA Stipend levels are too low and fail to factor in cost-of-living considerations. In regions with high cost-of-living, NRSA stipends are half of what an entry level scientist is offered in salary in the biotech sector and benefits pale in comparison. The observation that NIH intramural post-doc stipends are higher than NSRA-set levels are evidence that the NIH is well aware that NSRA stipends are uncompetitive in some regions. The NRSA stipend levels are used by many extramural institutions as a benchmark for stipend levels for all postdoctoral trainees in order to have parity, regardless of source of stipend/salary, so this has a broad effect on compensation of all postdoctoral trainees. Although some institutions allow investigators to supplement the stipend beyond the NRSA level, these additional funds can only come from non-federal sources, which are very limited in most circumstances. If laboratories in high cost-of-living regions or regions with a robust biotech presence are to successfully compete for trainees, the current system of a single NRSA scale across the nation must be changed and NRSA stipend levels must be increased with a sound plan for funding these positions.
2) The NRSA requirements of citizenship or permanent residency substantially limits the pool of potential trainees. Most US investigators receive many more applications for training from individuals not eligible for NSRA mechanisms because they are foreign nationals. We should have mechanisms for supporting training of highly educated, motivated, productive young scientists who are foreign nationals, because this will expand the pool of potential post-doctoral fellows. Moreover, these are precisely the types of highly skilled, high performing individuals whom we should want to ultimately become permanent members of the US scientific enterprise.

Proven or promising external resources or approaches

No response

Response 1130

Perspectives on the postdoc roles and responsibilities

Postdocs generally look like more opportunities to pump out papers and acquire skills different from the phd. Ideally it’s an opportunity to receive mentorship and training to lead towards independence and establishing a new lab but I don’t think that is always the case.

Fundamental issues and challenges

There needs to be much much higher pay. As a biomedical engineering PhD, I can earn salaries commensurate with our skills and expertise. Benefits such as retirement funds, health insurance are also important. Relocation costs and bonuses will be more attractive overall. There is a lot of work to be done in my research, why would I opt to do more of that, earn less pay than industry with the empty hope of acquiring a faculty position or establishing my own lab when there are way too many PhD graduates than there are open faculty positions? One could argue, these positions should be only for the best of the best and weed out those who truly aren't "passionate" about the work. I do agree with this in some way but this tends to favor those from more economically privileged backgrounds. Do we really want socioeconomic background to be a determinant for staying in research and academia?

Existing NIH policies, programs, or resources

Admittedly, I did not know about some of these resources. One area of improvement could be in the dissemination of information about these resources/programs. Fewer acronyms in announcements and more graphical announcements through social media (if not used already) will help.

Proven or promising external resources or approaches

In my opinion, there need to be permanent scientist positions (staff scientist, etc). A position for PhD graduates who are not necessarily interested in opening a lab themselves but prefers to just perform the research labor and what comes with it.

Response 1131

Perspectives on the postdoc roles and responsibilities

The role of an academic postdoc is to expand upon PhD training to set a scientist up to start their own lab. This manifests by allowing them an environment and the resources to start their own independent research program under the guidance of their PI.

Fundamental issues and challenges

Biomedical postdocs have become prohibitively long and, coupled to the expectations for poor work-life balance and financial struggles, mean that postdocs often put off life events (having children, buying a home) until very late in their 30s. Many postdocs thinking about starting families have to make tough decisions between having "successful/productive" postdocs and having families. This is in part because it is challenging to publish (process takes a year or more), you spend much of the first year of your postdoc applying for funding, and often spend more time commuting in high COL areas. Additionally, the expectations for what postdocs have accomplished (in terms of research, outreach activities, and publications) have become higher and higher in recent years and are frankly unachievable for all but a small number of (often privileged) individuals. This creates a large mental health burden on postdocs and can be a large reason why many leave academia for other careers.

Existing NIH policies, programs, or resources

NIH could do a lot more to help postdocs, including:

1. increasing minimum stipends across the board, and calculating mandatory COL salary increases;
2. provide childcare subsidies and emergency grants or now-interest loans that struggling postdocs can apply for;
3. in high cost-of-living areas, mandate that universities with a certain amount of their research income coming from NIH provide housing to postdocs or subsidies to allow postdocs to live close to their place of work;
4. increase grant eligibility extensions for postdoc parents or those with disruptive life events, and make it easier to apply for such extensions;
5. put pressures on journals to change publishing practices such that papers don't spend months to years in the review process;
6. more evenly spread NIH grant funding out such that postdocs in less well-funded labs don't spend valuable research time applying for grants.

Proven or promising external resources or approaches

No response

Response 1132

Perspectives on the postdoc roles and responsibilities

It means I am climbing stairs to find myself in academic pressure or leave and get into industry which may have equal pressure but earn my bread without worrying my pocket.

Fundamental issues and challenges

If NIH can't improve the pay scale. Make the PostDoc job with fix timing frame, so that we gets an extra hour salary, then no PI will exploit their PostDoc employees

Existing NIH policies, programs, or resources

Fix time frame for PostDoc + salary hike of minimum 5-10% atleast after 2-3 year experience in same lab. When PostDoc works in same lab, he becomes standing pillar without her/him no PI can get Data for grant or papers

Proven or promising external resources or approaches

Please Fix working hours. After or during Ph.D. Most of the PostDoc who joins has a family, kid etc. Wihout fix working hour no one gets best work life and mental well being balance.

Response 1133

Perspectives on the postdoc roles and responsibilities

Viewed as a stepping stone towards becoming a PI. The role involves being mostly independent in your research, along with doing significant mentorship within the lab.

Fundamental issues and challenges

1) Pay is too low. Doing a postdoc becomes a trade off between getting to stay in academic research and being able to afford a home/family/middle class quality of life in areas like the Bay Area or Boston.
2) Fertility clock. As a woman, I worry significantly about the overlap between when it would be ideal to start a family (early 30s) and when I would be doing my postdoc (early 30s). I have seen having children significantly affect the progress of postdocs, even when they have full PI support. In addition, without adequate salary to pay for childcare, it puts a lot of pressure for one spouse to always be home with the child instead.
3) Job prospects. Becoming a PI is seen as very difficult, and cynically, seems to be most likely if you come from a few top famous labs. However, beyond being a PI, it doesn't seem like many jobs (industry, consulting, law, biotech, science writing or policy), really benefit or need a postdoc. So then it becomes a question of: should I spend 5 years doing a postdoc for a job that I'm unlikely to get?
4) Hierarchy. Doing a postdoc seems lowly valued. It's not a job people necessarily aspire to in itself—it's simply a stepping stone people seem to want to move through as quick as possible

Existing NIH policies, programs, or resources

I think simply raising the minimum postdoc pay

Proven or promising external resources or approaches

No response

Response 1134

Perspectives on the postdoc roles and responsibilities

An academic post doc is a waste of time. Given how few faculty positions are open.

Fundamental issues and challenges

Post docs get paid very little money for how much work they do. Can any of you at the NIH tell me with a straight face that you would do a PhD then move into to post doc to make 50,000 in places like th bay area or Boston.

Existing NIH policies, programs, or resources

Yes, post docs should make at least 90,000.

Proven or promising external resources or approaches

No response

Response 1135

Perspectives on the postdoc roles and responsibilities

I view the postdoc as primarily a stepping stone to increasingly rare opportunities to become an independent researcher in academia. It's an opportunity to develop your own research ideas and improve your track record.

Fundamental issues and challenges

It comes down to money. I have two young children and I cannot afford enough childcare to cover the time I need to work. In addition, to afford rent I have we now live far from work with a 2h total commute. In sum, I am not paid enough to work. This is aggravated by living far from family and friends that could help out with child raring.

The lack of funds and the need to scrape by (Eg literally planning which bills to pay and in what order because we do not have enough money in the bank account) drains a lot of energy that could have gone towards producing exciting research. It's really a disgrace.

Existing NIH policies, programs, or resources

Funding should be substantially increased (50% over current minimum). At a minimum it should be adjusted to local living expenses.

Extra funding on the range of 20k/year per child should be given automatically. This would probably make the biggest difference for most people.

Other form that, many foreigners deal with other expenses and things like green card applications could be supported both economically and practically by access to free legal help.

I realize funding is not endless BUT if this would lead to fewer postdocs being funded overall it's probably not a bad thing as the success rate would increase downstream for the postdocs.

In addition, more PhD programs should focus on "alternative" career paths.

Proven or promising external resources or approaches

Salary increase would solve pretty much all problems it would allow people with fewer means to stay in academia without sacrificing health and sanity.

Less postdocs overall would increase the need to fund new PIs better maybe by shifting funding from larger labs.

Response 1136

Perspectives on the postdoc roles and responsibilities

Cheap labor that usually now must also find its own grants to be granted the "opportunity" to postdoc in someone's lab. Who is then "trained" by managing students and equipment while writing grants and papers for the PI and being paid a fraction of the pay of counter parts in industry.

Fundamental issues and challenges

Crappy pay, crappy bosses, crappy workload—no time off, no maternity/paternity, no respect, and general exploitation.

Existing NIH policies, programs, or resources

Standard salary comparable to industry. Standard hours comparable to industry. Standard rights to time-off. MOST IMOPORTANTLY—the NIH should be reviewing all of these universities and PI's that are using millions of take payer dollars, making salaries of hundreds of thousands of dollars while paying postdoc and graduate student peanuts, and these trainees have no voice and no protection from these "mentors"

Proven or promising external resources or approaches

Anonymous website to submit complaints about professors and universities. Enforcement of far and regulated employment policies—wages, salaries, time-off

Response 1137

Perspectives on the postdoc roles and responsibilities

Training, full time job

Fundamental issues and challenges

Salary, ill-defined role

Existing NIH policies, programs, or resources

Increase stipend, more support, better definition of role

Proven or promising external resources or approaches

No response

Response 1138

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

My PI has tenure. He doesn't care about publishing. So I'm stuck 8 ears because he doesn't have time to look at my paper. He is teaching and has a company. This has to change.

Many of my postdoc friends left for same reasons. Pi not interested in sending out their papers. They send out papers of graduate students because there is a commette and they have to.

Postdoc need paper for faculty position. No papers, no faculty position.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

If multiple postdoc leave a lab there should be an investigations.

There is no protection for postdoc this has too change.

When I complained to the department head the answer was: PI know better.

Beside low salary that is a big issue I believe the other big issue is to be completely in the hands of one person : PI. If it's a training position this makes no sense. Some protection or checking on PI is required

Response 1139

Perspectives on the postdoc roles and responsibilities

I view my postdoctoral research position as an opportunity to apply the expertise I developed as a graduate student while gaining new skills in an adjacent field of study. Ideally, postdocs have a symbiotic relationship with their lab, by bringing in specific skills and techniques to share with other lab members while expanding their technical and conceptual toolkit with assistance from their host lab. Postdocs also serve an important role in training graduate students in both technical skills and the "softer" skills of scientific practice, such as data management, experimental design, and interpretation. I also consider the academic postdoc position as a launch pad for future career opportunities in both industry and academia. For better or for worse, as the duration of postdocs has expanded over the years from a quick ~3-year position to something closer to a second PhD (~5-8 years), this position now looks much more like a long-term job than a temporary training position. Longer postdocs certainly offer a benefit to labs by providing a more stable supply of subject-matter experts to retain institutional knowledge, conduct difficult experiments, and train new lab members. Unfortunately, the pay and benefits afforded to postdocs have not kept up with this change in the duration and expectations of postdoctoral researchers, and I often see both funding agencies and out-of-touch PIs dismiss postdocs as simple trainees, not as experts that contribute crucial services to their laboratories and institutions who could easily make 2-4x their pay outside of academia.

Fundamental issues and challenges

In my view, the single biggest and most important barrier to postdoctoral retention and recruitment is salary. Postdoctoral researchers are experts in their fields who are nonetheless expected to work long hours for 5-8 years for less than half the pay they would earn in other sectors. Especially in high cost-of-living areas, this pay is frequently too low to allow postdoctoral researchers to rent a one-bedroom apartment, let alone to support child-care costs. (When child-care supplements do exist, they are often laughably low, or tied to specific funding mechanisms, or only available to women [and not new fathers or couples adopting a child, etc.] which renders them only minimally useful.) The economic difficulty inherent to doing an academic postdoc reinforces other disparities in science, as this route can be prohibitive to scholars from lower-income backgrounds, especially given the prevalence of student loan debt, lengthy duration of postdoctoral periods, and the poor prospects for landing a well-paying faculty position on the other side. These issues are further complicated by the fact that many postdoctoral fellowships, while ostensibly good for postdocs' CVs, remove employee status and thus take away access to employer-

sponsored retirement plans, the best health insurance options, etc. Finally, it should be mentioned that international postdocs are in a particularly precarious position, and rampant abuse (maintained by threats of not renewing visas) has been well documented.

Existing NIH policies, programs, or resources

Postdoctoral funding mechanisms such as the F32 should be modified to allow postdocs to retain employee status. Taking away key benefits during what are often peak earning years (late twenties—mid thirties) places an undue financial burden on postdoctoral researchers, and further discourages researchers from lower socioeconomic backgrounds from pursuing postdoctoral training. Similarly, the payback obligation incurred by F32 funding is antiquated, unfairly ties postdocs to specific employment situations that are often abusive, and limits the mobility (economic, geographic, etc.) of postdocs funded by these mechanisms. Finally, the NIH should encourage institutions to establish uniform and transparent guidelines about postdoc pay scales based on local cost of living assessments (and to allow those guidelines to factor into budget descriptions in R01s, etc. if they don't already). I know faculty who claim that the NIH "doesn't allow" postdocs to be paid off NIH grants at rates higher than the NIH minimum, and use this as a justification to pay postdocs in their lab far below the rate that postdocs in neighboring institutions make.

Proven or promising external resources or approaches

No response

Response 1140

Perspectives on the postdoc roles and responsibilities

For me, I see the postdoc position in two lights from the experiences I have had. One, I see this position as an opportunity to gain expertise in a new field and to establish one's identity and independence in the scientific community. On the other hand, I see this position as a potential cyclic trap where one can linger and go from postdoc to postdoc.

Fundamental issues and challenges

Honestly, the pay is not sufficient when you look at trying to do a postdoc in California or east coast with the price of rent. It's very discouraging.

Existing NIH policies, programs, or resources

Programs to show post docs how to establish their own identity in their lab and outside mentoring apart from your postdoc advisor.

Proven or promising external resources or approaches

No response

Response 1141

Perspectives on the postdoc roles and responsibilities

A postdoctoral position is for a trained and skilled researcher, and is on par with senior research scientist positions in both academia and industry.

Fundamental issues and challenges

Inadequate pay. A postdoctoral researcher is highly skilled and trained. A barrier to recruitment and retention is a lack fo both a cost of living salary, and salary that accounts for their skill and contribution to the reputation, standing, and income of academic institutions.

Existing NIH policies, programs, or resources

Pay them their worth.

Proven or promising external resources or approaches

Pay them their worth.

Response 1142

Perspectives on the postdoc roles and responsibilities

Postdocs bear the responsibilities of faculty members (and then some!). Postdocs are expected to generate their own unique research direction that synergizes with the lab of their faculty 'mentor', obtain funding (which often results in loss of some or all benefits), mentor undergraduate and graduate students as well as junior postdocs, guest lecture in classes and labs, write primary manuscripts, reviews, commentaries, and abstracts, apply to conferences and obtain funding to attend said conferences, present at conferences, bring new techniques to the lab, review manuscripts, and (often) perform lab management tasks such as: repair/coordinating repair of equipment, order reagents, develop/maintain lab organization, safety, and cleanliness standards, perform routine checks on lab reagent/equipment status, and ensure continuity of research methods. Additionally, they are expected to generate enough data to publish at least one (usually more than one to be competitive) first author manuscript in a short period of time.

Fundamental issues and challenges

Postdocs are taken advantage of. Postdoc experience/publications are needed to gain faculty positions, but only the independently wealthy can realistically afford to do a postdoc. The number one challenge to postdoctoral researchers (I vehemently disagree with the term "trainee" being applied here, few postdoc programs offer any kind of training—postdocs are self-taught or "mentored" by their PI, who has zero mentoring training) is financial. Consider this most basic recommendation for financial stability—at age 30, you should have the equivalent of 1 year of full salary in a 401K or similar retirement plan. Postdocs, who are often 30+ years old, are often not even provided access to a retirement account. They are also rarely

Existing NIH policies, programs, or resources

- Funding of staff scientists. Postdocs should not bear every burden of a PI and lab manager. Further, there need to be options in academic research other than Faculty or Fail. Funding staff scientist positions would allow people who love academic research to stay with financial stability. It would also greatly improve scientific rigor. How often do labs 'lose' techniques/things stop working after big turnover because the senior grad students moved on and the postdocs left? What does that say about your science if even your own lab can't reproduce its own finding? Staff scientists would provide continuity and expertise when training new members.
- Required mentorship. The F32/K99 grants are meant to serve as "training" plans, but they are made up. I know many F32 recipients (10+) and not a single one of them spoke to their mentoring "committee" after receiving their award. If the NIH wants postdocs to receive mentoring, then F32/K99 awards should have required mentoring or training checkins that are solicited from NIH DIRECTLY to the mentoring committee. This would ensure that the postdoc isn't just asked to write up their own summary/letter of support/etc. as often happens. They could require a visiting scientist position to learn a new technique or regular conferences put on by NIH to address how to apply for faculty awards etc. These things need to be MANDATORY. Postdocs are overburdened, and their personal and professional development is the first thing to go when they need more time.

Making these mandatory would ensure

- only people who are committed to academia apply and
- postdocs actually receive the training that they pretend to get now. The NIH should also make sure that any PI who has an NIH-funded postdoc in their lab receives mandatory formal training in mentoring, bias, career support, etc.

Proven or promising external resources or approaches

The best programs I have seen so far (I wish they had existed when I was looking!) are the postdoc-faculty positions. They provide a stricter timeline, better financial stability, real benefits, and personal stability, as you are not expected to leave and find a job elsewhere after a few years. Plus, you are actually learning how to be a PI in the very place that you will become a PI! By the time your lab "opens", you will already have collaborators, you will know how graduate student recruitment works, you'll know the grants management teams, you'll know the institutional and department benefits, and you'll already have animal protocols/space set up so that you are ready to hit the ground running, and you don't waste a year "setting up" a million+ dollar lab while you spend a month figuring out how to order pipette tips. NIH

should absolutely fund more of these positions, and not put the onus on wealthy institutions to decide to do them. Call it a 'postdoc in place' or something. In all honesty, I think graduate programs should consider these positions too. Once you're in your last year of grad school if you love where you are and you want to stay, you should be able to apply. Having to move 2+ times just to get a faculty position is a huge financial and personal barrier.

Response 1143

Perspectives on the postdoc roles and responsibilities

A postdoc is meant to be additional training to prepare for a career. If I already had all the training I needed after my PhD, I would have gone directly to employment. In my case, I wanted to switch fields. It shouldn't feel exploitative or like a major sacrifice. We are adults just trying to make the world a better place.

Fundamental issues and challenges

Postdocs do the vast majority of biomedical research in this country and we are not paid nearly enough. This is in terms of our level of education, what we contribute, what we could get paid in a non-academic position, and relative to cost of living. This is a major problem for competitiveness and ability to attract postdocs, but it is also a diversity, equity, and inclusion problem. As chair of my postdoc association, I heard of and witnessed many postdocs leave academia for industry positions because they could not afford to raise children on the low postdoc salary. It is easy to get an industry position after just a couple of years of a postdoc, but academic positions require a more extensive CV and much more time. By keeping postdoc salaries low, the NIH is forcing postdocs from low SES backgrounds, costly health issues, and caregiver responsibilities out of the academic track, and those with elite backgrounds and parents who still partially support them are able to continue on to academic careers. Additionally, by not changing R01 funding levels, the NIH is pitting postdocs against their PIs. PIs cannot afford to pay postdocs more, even if they recognize the problem, and unfunded mandates from institutions or the NIH for higher postdoc salaries does nothing to fix the underlying problem. The US needs to value scientific research appropriately, both through direct spending of taxpayer dollars and by recovering funds from the pharmaceutical industry that profits off of work performed in academia. Until this is fixed, everything else will be a bandaid. But in the short term, if postdocs don't get paid more the system is going to collapse.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

I am paid by HHMI and my salary is so much better than the NIH scale. They also give bonuses occasionally and I have great healthcare. This makes me feel valued and like I can make choices about my postdoc and career on the basis of variables beyond whether I can afford to live. They also are on the cutting edge in terms of DEI.

Response 1144

Perspectives on the postdoc roles and responsibilities

Temporary position that allows me to have greater influence and ownership of my research relative to my PhD. The primary value of a postdoc is the ability to be eligible (in practice) for an academic position. For some, it is about getting exposure to a more well-connected biotech network to non-academia and this primarily means Boston, Bay Area, San Diego, or Seattle. For instance, while there are great schools in the midwest, they are generally less connected to biotech private sector, meaning moving to one of the above locations is incredibly important to have an easier shift to the private sector.

From a lab-perspective, postdocs are generally hired to perform versus learn. There are pros—and cons—to this. It makes it less of a "traineeship" position and I don't think many labs treat it as such.

Fundamental issues and challenges

There are two huge challenges.

The first is pay—while the NIH minimum payscales are potentially appropriate for lower cost of living areas in the country, this is not true for the areas of the country where having a postdoc position is most useful (see above).

The second is life-planning—this is related to pay. It is difficult to consider planning a family if you're barely able to save money while you're in your late 20s, early 30s and do not where you will be able to live in the long run. I'm not sure how the NIH could change this.

Existing NIH policies, programs, or resources

Increased minimum pay for postdocs and increased cost of living adjustment. The NIH payscales are far too low for how much

1. academic research is dependent on postdocs and
2. moreso for where it's best suited (careerwise) to do a postdoc (ie high cost of living areas).

There are a lot of general problems like the over-competitiveness and lack of job stability that are generally needed as well, but I don't see how the NIH could solve those issues. These seem cultural more than something policy can change.

Proven or promising external resources or approaches

I think the data generally show that people are far happier and willing to take positions that are paid for in exposure or training if they are paid enough in USD.

Response 1145

Perspectives on the postdoc roles and responsibilities

In my opinion, postdoctoral position provides additional research experience which can help to implement the earlier experience to another field. During postdoctoral studies, researcher can expand her/his skills in another field while providing different skillset. In addition to exploring new field of research, during the period, reseracher should enhance the experience of writing grants, mentoring skills, and administrative skills. Overall, postdoctoral position means the period of time that the researcher can learn different skillset, writing grants, improve mentoring and administrative skills.

Fundamental issues and challenges

There are a couple challenge I would like to address to improve the quality of postdoctoral studies as an international women researchers. Firstly, postdoctoral reserach trainees paid very low in the current economic condition in the U.S. Especially in metropole cities most of the postdocs are living either in unsafe places or shared houses. Secondly, most of the reserach laboratories have very toxic environment due to the lack of control mechanisms of principle investigators. Except very few of PIs have the mindset of providing the supportive environment for postdocs to improve themselves. Based on my understanding, the main focus of PIs is meeting the progress report deadline and continue the grant which results an very abusive culture in academia. Finally, due to the lack of leadership and other soft skillsets, traniees expose to different kind of harrasment and abuse. It is more common in international reseracher due to the visa restrictions. Some of the PIs preffered to hire internationals on purpose to force them work extensive hours and weekends.

Response 1147

Perspectives on the postdoc roles and responsibilities

A chance to develop leadership skills in an academic lab and work towards an independent research program. A stepping stone to an established academic or government career. Unfortunately though the PI I chose to do a postdoc with, though a well-respected scientist and mentor, treats the position like a cheap lab technician/research scientist furthering their own research program. I have found my path to independence stifled.

Fundamental issues and challenges

Money. As a postdoctoral fellow not only is my pay not competitive and barely enough to live on, I also don't receive any benefits other than student health insurance. I am unable to save appreciably for retirement and am intelligible for benefits from the university. I also do not qualify for any government benefits such as FMLA or disability. Though postdocs have terminal degrees they are viewed and treated like temporary workers and often have student status rather than respect as highly trained scientists.

Existing NIH policies, programs, or resources

Family leave policies need to be updated to reflect a more human treatment of families and especially mothers. This cannot be left up to the universities because they are not providing adequate leave. The sexism and antagonism I experienced as a postdoc during my pregnancy and meager maternity leave broke me and is partially responsible for my leaving my postdoc and academia. There is little to no support infrastructure for parents for people in a position that they are taking during their childbearing years.

Requiring postdoc appointments to not be categorized as trainees/students in the university system to allow for real benefits and employment status both through the university and federal government

Proven or promising external resources or approaches

Required training for mentors. Oversight of mentoring. Real, appreciable ways to report gender based discrimination in mentorship or a system of reporting/warning others of bad experiences with mentors.

Response 1148

Perspectives on the postdoc roles and responsibilities

As I see it there are two "types" of postdocs. One is a postdoc focused exclusively on additional training and a second is a postdoc focused on assisting in conducting the work of a PIs externally funded studies. Both postdocs focus on transitioning the individual to the position of an independent investigator and often include crafting early career training awards (e.g., K01, K99/R00). Both types of postdocs have their pros and cons.

Fundamental issues and challenges

The major issue with training-focused postdocs (e.g., T mechanisms, F mechanisms) is the salaries which are just too low. They are also somewhat constrained particularly when a trainee is ready for independent work and doesn't necessary need additional extensive training. Instead, I write postdoctoral research associates into my grants. I can pay them more than they would make in a training mechanism, they have tremendous opportunity to learn about running large grant-funded projects and writing grants, and they can still do their own independent work and get assistance writing their own K.

Existing NIH policies, programs, or resources

Increase salaries and research funds for T and F mechanisms.

Proven or promising external resources or approaches

No response

Response 1149

Perspectives on the postdoc roles and responsibilities

Can mean many things, depending on the career goals of the postdoc. Usually involves additional training, often includes doing studies that were initiated by the PI (ie work for the PI), sometimes involves independent research initiated by the postdoc. Postdocs often serve as mentors to more junior members of the lab.

Fundamental issues and challenges

No response

Existing NIH policies, programs, or resources

Response 1150

Perspectives on the postdoc roles and responsibilities

A semi independent scientist that is able to work autonomously on projects that contribute to the overall lab direction. For those hoping to advance in academics, nearing the end of the postdoctoral fellowship the trainee should be committing a significant amount of time for an independent project that they would take onto their own lab. Tor those aiming to remain as high-level research scientists, their work should be a high level but focused on lab goals. For those post docs hoping to work in a career trajectory outside of academia, the last part of their term should be focus on developing the skills that would make them successful in that career tract, i.e. patent lawyer, consultant, etc.

Fundamental issues and challenges

Number one issue: SALARY. There are so many students do you want to leave immediately after getting their PhD and work in biotech making six figure salaries. This perspective comes from serving on three different admissions committees in one of the top medical schools in the country. I interview more students I can count each year. From the beginning, a growing number of students are focused on alternative tracks that don’t require a postdoc. In large part a significant motivator for moving outside of academia and postdoctoral fellowships is the amount of money that can be made in the private sector. Second, our grants do not support being competitive in this hiring environment. Lastly, the increasing difficulties faced by faculty in maintaining grant support and the decreasing purchasing power of our grants certainly demoralizes the students and discourages them from attempting to go into academia and thus doing a post doc. While NIH/NRSA salary lines continue each year to improve, there is no concurrent improvement in the modular R01 and any adjustments in my budgets to accommodate increasing pay for my postdoctoral fellows or to adjust for inflation are removed at the IC.

Existing NIH policies, programs, or resources

Increase overall salaries for PDs as well as the monies given out in grants to support postdocs. The modular R01 budget is a joke. We are being squeezed from all sides. How can I honestly tell my post-docs that academia is a good choice. My purchasing power keeps getting cut back by inflation and increasingly restrictive funding policies at each IC. That means I can only pay for a few or post docs and I can’t pay them what they are worth. Postdocs and senior students see these consequences first hand and many are happy to jump ship to the private sector ASAP.

Proven or promising external resources or approaches

Money.

Response 1151

Perspectives on the postdoc roles and responsibilities

Postdoctoral training is the training period where a trainee advances from learning how to be a scientist (graduate school training) and begins to learn how to actually run a laboratory enterprise as a primary investigator. The training should cover all aspects of skillsets needed to be a PI but most especially: grant writing (by securing your own extramural funding), mentorship by mentoring students in the lab or teaching courses, concrete laboratory and research management skills.

Fundamental issues and challenges

Postdoc salaries are the biggest issue. As an American citizen who did all of my education at public institutions in the USA the postdoc salary does not address the crippling amount of student debt American postdocs are suddenly hit with when we lose student status. I think this is often in sharp contrast to international postdocs, especially those who were students in Asian and Europe and then only came to the USA for postdoctoral training. Really though all the things that are major issues for domestic and international postdocs could either be bandaged with handouts or subsidies targeting a specific issue from the institution where the postdoc is training; or the postdocs could just simply be paid more, with a COLA (cost of living adjustment) factored in, and just be given more control over their situation which would give postdocs the power to just make the best choices for their own life as they advance through postdoctoral training.

Existing NIH policies, programs, or resources

I would like NIH to do more to help SGM (sexual and gender minority) postdocs. There is a need for SOGI (sexual orientation and gender identity) data to support SGM postdocs being included in opportunities for under-represented/under-privileged folks. I also think that the NIH should do more to promote having domestic postdocs over international postdocs (perhaps by even by augmenting how R, T, K, and U grants are structured). I am currently a postdoc at one of the 3 major medical centers in [redacted for anonymity]. My institution is >75% international postdocs because most domestic postdocs are put off by how unmanageable the finances are here. This also represents a huge brain drain as most of these postdocs at my institution just go back to their home countries taking all that training and talent back out of the USA.

Proven or promising external resources or approaches

I have really benefited from doing two postdocs at institutions that had an official office of postdoctoral affairs and a postdoc association. To the extent that i almost always advise grad students to NOT do a postdoc at an institution that does not have an official office of postdoctoral affairs. I have also noticed that postdocs at institutions with unionized postdocs fair much better than postdocs at institutions, such as mine, without unions. The NIH would do a great service to postdocs by providing more postdoc specific training modules to supplement what is not available at institutions that lack an official office of postdoctoral affairs. If the NIH had a public database of postdoc salaries by institution I think this would provide a great source of leverage for postdocs to have better pay equity.

Response 1152

Perspectives on the postdoc roles and responsibilities

I was a postdoc at a national lab for 1 year. I pursued a postdoc because industry was not hiring when I graduated and I needed to "park" myself somewhere until more jobs were available. I also wanted to use the postdoc to re-evaluate my choice to pursue industry after being in a different environment from my PhD. I chose where I did a postdoc because there were very specific skills that I wanted to gain in an area of science I wanted more experience in. I also selected my postdoc due to the prestige and large number of collaborations of the PI. In many cases, postdoc positions are good ways to get the "blessing" of a big name PI to help get academic interviews/job offers and many friends picked postdocs for that reason more than the skills that they would gain. In my field (chemistry), postdocs are a de facto requirements for applying for faculty positions, regardless of how competitive the applicant is.

As a postdoc, I expected that I would be able to apply the skills I gained in graduate school to problems in a new field while learning techniques in that field. I also thought I would be responsible to be a role model for and help train the grad students (i.e. bring in outside knowledge to the group). However, since being a postdoc is not a sustainable position, there is no incentive to train younger students when you could be spending that time on completing projects and applying for jobs. I also felt that my role was to learn the key skillset of the lab quickly to either complete a project or start one that could be handed off to students to continue to build out after I left.

Fundamental issues and challenges

A huge problem about being a postdoc is that it is not designed to be a good experience. Postdocs are underpaid, over-worked, and stressed about whether there will be a job at the end because it feels as though there are far less jobs than people competing for them in both industry and academia. A career path at a national lab seems to operate by "work for someone and hope they like you enough to suggest hiring you on full time." Given this, if a permanent job was available at the end of a PhD, there is little reason to pursue a postdoc short of it is a requirement for academia.

The start of a postdoc is stressful—you are expected to be an expert but since it is new area, you aren't an expert yet. You also need to learn how to function at a new place so it is hard to be productive. That causes stress due to a growing expectation of what you should have accomplished within the time you have been a postdoc. That is: if you have been in a postdoc for 3 years with nothing to show for it (i.e. bad projects, etc) you will be viewed as unproductive so it will become increasingly hard to leave. Therefore it is incentivized to get out quick on the strengths of grad school work or achieve something fast and get out or stay until a high-impact accomplishment can be achieved then leave immediately.

The temporary nature of a postdoc prevents settling down since you could be moving across the country in a year or so.

Also, having a fellowship seems to be expected but having one makes doing taxes painful or changes your status at your institute which can change if you get healthcare, etc.

Existing NIH policies, programs, or resources

NIH grants could pay more to make postdoc salaries more competitive with industrial jobs. If the salary difference between a postdoc and start-up was only 5-10k, the choice of pursuing a postdoc might be more tenable, particularly for those with children. Alternatively, the NIH could tie salary to cost of living in a given area. My NIH fellowship would have been super easy to live off of in many places but, where I was, the cost of living was high enough that to have a reasonable quality of life, I ended up saving very little.

In addition, an NIH-sponsored conference where postdocs on the job market could present to faculty from departments which are hiring would be extremely useful. AIChE (the professional society for chemical engineers) has a poster session explicitly for this purpose every year and it is very helpful for giving candidates greater exposure on the academic job market. There should be support for candidates to attend so it does not just turn into another forum for only people from wealthy/prestige labs to get jobs.

One reason I did not pursue an academic career is that getting funding for research appears challenging (especially for young PIs) and many of the prestige grants can barely support 1-2 students. It felt that unless I could be at the top schools where there is lots of internal money to support research, it would be exceptionally hard to support a research group, especially because costs for everything have increased dramatically and the amounts awarded remain flat.

Proven or promising external resources or approaches

Response 1153

Perspectives on the postdoc roles and responsibilities

Cheap expert labor for another scientist with the hopes of opportunities for career advancement and placing into a tenure track position.

Fundamental issues and challenges

As an MD-PhD going into research, I should not be "enticed" into a postdoc at [redacted for anonymity] by being told my NIH minimum salary will allow me to "qualify for low income housing and food stamps" in [redacted for anonymity]. If the US values its scientific dominance as it should and wishes to maintain it, we can't be making life as an academic scientist untenable, especially when other more lucrative opportunities are abundant in industry, where the work we do may or may not be in the public or nation's interest.

Existing NIH policies, programs, or resources

Labs cannot afford to pay postdocs what they need to raise a family, especially female scientists in their 30s whose maternity clock is at its end. NIH must increase its funding for postdocs and investigators to be able to support a reasonable minimum in cities where most high impact science is happening—salary in the 90k+ range plus benefits (health insurance, dental, vision) is essential

Proven or promising external resources or approaches

It's 100% money, man. Pay us.

Response 1154

Perspectives on the postdoc roles and responsibilities

Postdoctoral training is an important level of our career where we develop our expertise in our fields of interest. We get further training that helps us establish ourselves in our chosen career path.

Fundamental issues and challenges

Promoting basic research is very important which is declining because of lack of funding. Challenges that postdocs are facing is losing jobs due to lack of funding in the lab that they want to continue.Moreover this is again taking away all the time that they had given to that lab. This effects the cumulative time that a postdoc has to apply for K-grants in their career specially for internationals or non-citizens who wants to be an independent investigator. These unpredictability and a feeling of insecurity also is effecting mental health of postdocs. A lot of early career investigators are also moving towards industry due to funding crisis.

Existing NIH policies, programs, or resources

The most important suggestions that I have for NIH is to

1) Increase funding not only give multi PI grants but also single PI grants
2) If possible relax the time-line for K99 deadlines from 4 years of cumulative postdoctoral experience to 5 years.
3) Introduce postdoctoral fellowships for internationals and non-citizens
4) Make sure if the postdocs are paid the amount they deserve according to their year of experience. This also includes increasing funding so that the PI can pay the postdoc and support the lab

Proven or promising external resources or approaches

If possible organizing a training program for postdocs so that they know if they can reach out to write to NIH if there is any issue in the working environment or introduce a yearly survey system from the trainees on the mentor. This is an easy way to find out about the mentoring skills of the mentor, lab environment, and job satisfaction

Response 1155

Perspectives on the postdoc roles and responsibilities

It's a transitionary training period where I pick up skills/expertise to complement those learned during my PhD prior to achieving a permanent, full time position.

Fundamental issues and challenges

Currently, it seems postdoc programs are trying to simultaneously

1. provide additional training to recent PhDs and
2. support the backbone of highly skilled labor.

These are two fundamentally different goals and should be treated as different programs by the NIH — much of the dissatisfaction with postdoc life is being given professional obligations, while only receiving trainee benefits and salary.

Retention in the sciences appears high. Retention in academic research is gated by the number of permanent positions available (i.e. tenure-track, staff scientist, or other permanent roles). The scarcity of these careers, combined with how a postdoc is unnecessary for many transitions to industry, appears to be driving the scarcity of postdocs and to be a major source of dissatisfaction.

Frustratingly, the trainee benefits are often insufficient. For example, individuals who receive an F32 NRSA often take a pay cut because they switch from employees (who receive health care and retirement benefits) to fellows (who receive neither). Salary is also lacking relative to industry, which contributes to the shortage and disincentivizes individual's from continuing their training, especially if they have dependents to support. Personally, I believe that postdocs should be paired like the highly trained professionals we are, and that should be enough to live in any location in the country. I do not believe in a regional cost of living adjustment as I think there should be some financial cost to living in a highly desirable location and, conversely, some financial benefit to living somewhere with cheaper cost of living (this would also incentivize spreading excellent academics around the country rather than increasing the density in Boston and the Bay Area).

Existing NIH policies, programs, or resources

Change the F32 from a "fellowship/stipend" system, to a system where fellows remain university employees and that also pays benefits/fringe.

Clearly differentiate two classes of postdoc scientists —trainees who may be supported yearly and are capped at 3-5 years experience, and staff scientists. Provide funding mechanisms to support long-term scientists, such as an extension of the MIRA or other awards. I think it's particularly important that these jobs be able to guarantee long-term support rather than annual contracts —maybe make it a 5 or 10 year award for salary that is jointed applied for by the individual and a tenured sponsor. Research funds would not need to be included. I think this long-term stability is necessary to make staff scientist positions a viable alternative to tenure-track life.

Proven or promising external resources or approaches

No response

Response 1156

Perspectives on the postdoc roles and responsibilities

To me, it's a time to gain more independence and try on different hats so to speak—in a guided fashion gaining experience in teaching, mentoring, university service, setting up lab space, etc while learning more about the general university structure and diversifying your skillsets

Fundamental issues and challenges

As you'll see below, the continued financial sacrifices faced by postdocs (especially those on fellowships who lose staff/employee status) significantly impacts quality of life. Overall low pay and especially lack of raises (though faculty typically do receive them and in many places graduate students as well as they gain more experience) drives many to look for alternative, higher-paying positions. This is exacerbated when considering many postdocs are in stages of life where they might like to marry, begin or expand families, or procure more stable housing. There in an invisibility that comes along with being a postdoc both generally and more specifically on some of these tantamount issues that affects recruitment, retention, progression, and quality of life.

Existing NIH policies, programs, or resources

The F32 is, unfortunately, in need of massive overhaul. To be successful in grant writing only to lose out—loss of benefits (medical, dental, death benefits, retirement, etc), university support, the added stresses and red tape that receiving the grant adds—and then to feel completely trapped in that situation by the

payback agreement is simply wrong. Unfortunately my specific university had no publicly listed policies about these changes taking place upon becoming a fellow, leaving me blindsided amidst the pandemic with no insurance (had been eliminated months before they alerted me but was still paying premiums), no more retirement, and was no longer able to access many of the support systems granted to staff. Had I known the changes, I never would have accepted the award and I now actively discourage others from applying for the F32, as do many people (postdocs and faculty) in my department. We have already made choices with significant consequences regarding finances and security in order to become PhDs, and it seems unjust that we are still placed in situations where in order to be successful long term we must make more financial sacrifices. We are heavily encouraged to apply for and receive this grant mechanism (sometimes our jobs are contingent upon doing so) but the price is unreasonably high—in some cases the stipend is lower than the original salary and supplementation can be difficult or impossible, it often results in being reclassified as not a staff or employee, which jeopardizes several benefits we have worked so long and hard to achieve after delaying them to get a PhD in the first place. The system as it stands now is disincentivizing and completely antithetical to the aims of a fellowship.

Proven or promising external resources or approaches

I strongly suggest that the NIH find ways to adjust their policies on fellowships to ensure that it does not cause postdocs to lose out on finances and institutional support.

Response 1157

Perspectives on the postdoc roles and responsibilities

When I started undergraduate research I had ambitions of at least working my way up through a post-doc, then pivoting toward academia or industry based on my life circumstances. I thought that research was a great way to spend my time and make a living. I have a love of asking questions, designing experiments, and doing lab work. I had a great PI, was accepted as a Fulbright fellow, worked as a lab manager, and started on my PhD. A path with good potential to continue doing research for the rest of my career.

However, my attitude completely changed in 2018, prior to the COVID-19 pandemic. For me it was a personal reason, I was getting married. After doing the math, there was little possibility I could support my family on a post-doc salary. Not having parental support and even with combined incomes it would be challenging, although not impossible. Fast Forward to 2022 and the economic fallout from the pandemic and a post-doc position became a financial impossibility for me.

Fundamental issues and challenges

Hopefully you understand that the problem is money. You have to pay people more. Plain and simple. It is insulting seeing such low salaries and low benefits for what is a grueling, high-pressure position with an very uncertain outcome. You are asking people to postpone their lives for 2-6 years after already spending 8-12 years in undergrad and grad school. It is especially offensive when graduate students see positions in industry or in government’s GS tier that typically pay 80-100% more and are appropriately adjusted for cost-of-living.

Existing NIH policies, programs, or resources

If there was anything that existed here already, I don’t think the “post-doc-pocalypse” would be at our gates.

Proven or promising external resources or approaches

I am only going to make recommendations based on pay. If you cannot fulfill those recommendations, let’s be frank, you will not see an increase in post-docs unless the economic environment changes drastically for industry or government roles, forcing graduate students to accept low paying post-docs.

Hopefully you understand that the problem is money. You have to pay people more. Plain and simple. It is insulting seeing such low salaries and low benefits for what is a grueling, high-pressure position with an very uncertain outcome. You are asking people to postpone their lives for 2-6 years after already spending 8-12 years in undergrad and grad school. It is especially offensive when graduate students see positions in industry or in government’s GS tier that typically pay 80-100% more and are appropriately adjusted for cost-of-living.

Response 1158

Perspectives on the postdoc roles and responsibilities

In theory, a postdoc is an opportunity to develop a unique line of research branching off of an established PI. It is like a second shot at a PhD but with the training wheels removed and allowing a greater emphasis focused towards purely the research record —what a PhD might have been if all the lessons the scientist had gained were there from the start.

Fundamental issues and challenges

The single biggest issue is pay.

I went to undergrad, taking out $40k in loans despite having state, federal, university, and private aid that most people would not even be eligible for (uniquely low income/background of homelessness).

I did a PhD, being paid less than what a fast food job pays while being treated fairly poorly by the academic system.

I have a uniquely advanced understanding of molecular biology (by training), statistics/bioinformatics/machine learning (self taught + elective graduate coursework). Why would I ever accept being paid less than my friends made right out of undergrad with non-STEM degrees?

The funding for personnel on grants is far, far too low to retain me.

The idea of dealing with the utter toxicity of academia for pennies. Having to move every 5 years to "enrich my breadth of experience." to fight for an almost non-existent pool of faculty jobs is ridiculous.

I doubt that the NIH will ever have the funding it would need to both pay for the research materials needed to do work and also increase the paylines enough to make academia even remotely compelling.

Existing NIH policies, programs, or resources

Minimally, doing a 1-2 year postdoc should at least offer full student loan forgiveness (no hurdles involving competitive grant apps) 5o offset the tremendous time put into our education if it is a strategic goal for the US.

Even better would be a pay bump foreveryone (grad students included).

Proven or promising external resources or approaches

None of these things address pay.

Though the NIH could do better to address toxic, publish-or-perish attitudes.

Instead of having virtually daily reminders about how even a small mistake could technically be research misconduct, or how you are doomed if you don't have endless awards based on research outcomes that relied partly on luck.

You could implement ideas that involve positive feedback for everyone.

See this article https://hbr.org/2019/01/are-your-high-expectations-hurting-your-team

Response 1159

Perspectives on the postdoc roles and responsibilities

Postdoctoral research for me should be a training where I will learn how to be a good leader, a caring and dedicated mentor and an independent scientist. It is where I shouldn't be treated as a student or as a fancy technician. It is where I should have time not only to work on my lab project, but where I should have time to think about next projects, who to collaborate with, and where to go next.

Fundamental issues and challenges

Currently, I work an average of 16h/ day, my health has decreased exponentially, I haven't seen my family and friends in a normal frequency and I am paid so little, I can't afford paying my credit cards. There's always so much in my plate that I cannot even see the end of my todo list. I don't have a social life and nobody above me seems to care. I only hear that this is how it is to be a postdoc and if I do not do this I won't have enough publications to get a job. My boss is also overwhelmed and consequently they

delegate their tasks to Postdocs, making us work as a PI, as a postdoc, as technician and as a trainee in a constant basis. All those are things that make me want to quit in a daily basis and I can see that many of my graduate and undergraduate student peers recognize that, which makes them not consider an academic career.

Existing NIH policies, programs, or resources

We need to increase the value of all grants. The R01, for instance, is the exact same value since the 90's, so it is definitely outdated. The increase in the value of the grant would make everyone's lives easier. Also, NIH needs to make the possibility of getting a grant a bit more feasible. The competition to get a grant, publications and other prizes has become life consuming to a point where it obligates people to overwork their Postdocs and puts Postdocs in a position where they don't have many choices but to accept such treatment. In addition, the NIH should make a policy encouraging universities to give their Postdocs a raise when they are awarded grants. I was made aware this fall that this is not the case and my university would not give me a raise if I got a grant because there's no law/ rule that forced them to do this.

Proven or promising external resources or approaches

The NIH should enforce confidential lab reviews to evaluate lab managers and PIs, with real consequences for those who are evaluated poorly. There should be a limitation on work hours for Postdocs, with well established rules for extra work hours, maternity/paternity leave, weekends and off-hours contact. Lastly, mentoring should be a top priority of NIH, and real mentors or PIs that dedicate their time for mentoring should be more praised and recognized.

Response 1160

Perspectives on the postdoc roles and responsibilities

Opportunity to express freely my ideas and approaches to tackle challenging scientific questions in my field. Opportunity to have guidance for an experienced researcher and not be guided by a manager.

Fundamental issues and challenges

Decent salary (starting minimum at 80k) and administrative inclusion within the society. Remove the non sense J1 visa which gives no career projection but instead produces stress. Should give H1 visa with the possibility of green card.

Existing NIH policies, programs, or resources

H1b visa and Easy access to green card if postdoc is near the end of it's program. It will give the possibility to apply for faculty positions. Remove J1, it's rules are absolute none sense.

Proven or promising external resources or approaches

Postdocs must be suggested by their mentor as reviewer for a minimum of 2 journals, must be trained and submit a minimum of 1 internal grand and one national grand applications.

Response 1161

Perspectives on the postdoc roles and responsibilities

Post training is an integral step towards becoming an independent scientist, must do step if circumstances allows!

Fundamental issues and challenges

1) Low income even when inflation is at it's peak. Your mind debates between family or research and in the end, deviates you from the research oriented mindset to highly paid industrial jobs.
2) Immigrants did Ph.D from USA face difficult visa situations specially Indian Origin people because of visa back logs. J1 visa is not a dual intent visa if researcher wants to settle down in USA after post doc it takes years to get green card even when you have contributed so much in science.
3) In order to attract the talent, perks should be higher than industrial counterparts.

Existing NIH policies, programs, or resources

J1 vida for foreigners

Low income

Response 1164

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

Being totally beholden to a single research mentor is the single worst part of being a postdoc. It makes our careers precarious. No matter the value or quality of our work, it can be discarded in an instant due to conflict with a mentor, a mentor relocating to a new institution, or health challenges faced by that mentor. I have seen so many of my fellow postdocs leave their positions without publishing their valuable and important work, all because of the absolute dependency that is forced upon us by current funding structures.

Another reason that I see my fellow postdocs leaving their positions early: postdoc salaries and benefits. I could literally double my salary today by moving to industry. And get dental insurance to boot. It is only because I don’t have dependents that remaining in academia as a postdoc is financially viable for me.

Existing NIH policies, programs, or resources

Cohort-model programs such as IRACDAs should be expanded to provide postdocs (especially URM postdocs) with community and training in skills other than research (communication, pedagogy, finance, etc.) that they will need in their future careers.

Proven or promising external resources or approaches

Postdocs, like grad students, need multiple mentors. There should be formal systems in place to ensure that every postdoc finds multiple mentors at their home institution, perhaps something analogous to a grad student's thesis committee. Every post-doc should have a back-up mentor, a PI at their institution who is formally committed to helping that postdoc finish their training if—God forbid—the postdoc's primary mentor should die, move institutions, disgrace themselves, prove abusive, etc. All of these things happen. Frequently. And postdocs suffer the collateral damage of their PI's misfortune or misbehavior. There should be grants and/or department funds allocated specifically for postdocs (and grad students) whose work is interrupted by something their PI does or suffers. A safety net so that good science and good scientists are not discarded, as happens so often under the current system.

Response 1165

Perspectives on the postdoc roles and responsibilities

Background: I was a postdoc from 2013-2019 and am now an Assistant Professor at an R1 research university doing basic neuroscience research. My lab has two postdocs, one international and one a US citizen. I view the academic postdoc as a time where a highly trained scientist can focus on interesting and productive science. I view postdocs as leading independent projects and being able to focus on their interests without the distractions of teaching, grant writing, taking classes, etc. In practice, a postdoc is a temporary stopover where the majority of scientists aim build their CV to be competitive for a limited pool of independent faculty positions. But I think everyone doing a postdoc knows that these jobs are limited, and these days all postdocs have a "plan B" if the PI route is indeed their "plan A". Common plan B's include taking an industry role after a short postdoc, or becoming a staff scientist or non-tenure track faculty, or teaching at a primarily undergraduate institution.

Fundamental issues and challenges

Of course the top issue is salary. The median postdoc is an adult in their late 20s/early 30s with a personal life, perhaps thinking about having kids or already has kids. Low salaries especially drive women out of science at this career stage. Recruitment, retention, and quality of life all come down to salary and anything else is just tangential. Make salaries and benefits competitive, and these problems will improve. My gut says that the market rate for a starting postdoc should be ~80K, and this even represents a steep discount from what many PhDs would earn in industry. But the challenge here is that NIH cannot simply expect labs/institutions to support 80K+ postdoc salaries (what they deserve) without a major change to the typical R01 budget. The amount of $ in a modular R01 has not changed in years. But without a major increase in NIH funding overall, increasing R01 budgets would decrease the number of grants awarded. I think that increasing direct funding mechanisms to postdocs (e.g. by expanding the F99/K00 mechanism, below) could be one way around this difficult problem.

Existing NIH policies, programs, or resources

I think expanding the number of F99/K00 awards would be a great way to increase postdoc salaries without putting as much of this burden onto individual lab budgets. A crop of funded K00 postdocs would be highly sought after. Labs would compete over these postdocs. Even if NIH salary support is in the ~60K range, investigators would be able to compete by supplementing support from 75% to 100%. This would get postdocs from 60K to 80K without costing PIs a fortune and without requiring dramatic changes to R01 funding rates or budgets.

I also think that F32 and T32 eligibility should be expanded to include international postdocs. Really, any effort that enables NIH to provide direct grant support to postdocs will indirectly increase postdoc salaries by lowering the salary burden on individual labs and allowing labs to supplement funded postdoc salaries.

Response 1167

Perspectives on the postdoc roles and responsibilities

I view the academic postdoctoral position as the 'next step' after getting a PhD. It is only a useful step if you are working towards a tenure track professor job. It is useful for expanding your academic training. It is a nice segue between the structured, more supervised research of graduate school to larger, more self-determined research paths. As it is now, I would recommend it only towards those interested in pursuing a tenure track position, therefore there should be significantly fewer postdocs.

Fundamental issues and challenges

The postdoctoral position as it exists now only serves to advance academic careers towards tenure track positions. However many (if not most) labs rely on postdoctoral scientists to function, in many cases multiple postdocs. It is a temporary position by nature, with low pay and no internal advancement possible, yet most postdocs stay over 3 years because its simply not feasible to develop the CV necessary to advance to a tenure track role. Furthermore, since there are simply too few tenure track positions relative to the number of PhDs trained, those who go on the market early are often competing with other postdocs who have many years of experience (the three most recent hires in our department spent 7-9 years as postdocs). The fundamental issue is the system relies on a pool of highly trained, underpaid, yet dedicated academics who are vying for an incredibly limited number of jobs and their career network is composed of academics who likely have a good deal of confirmation bias. Furthermore, the work is mentally taxing, especially if you don't have the financial stability to afford things that can make challenging jobs easier (i.e. long commutes, strict budgeting, small apartments).

Existing NIH policies, programs, or resources

Decrease the size of PhD programs. If you do not have the money to support highly trained scientists, reduce training for these roles. If you do have money, increase the wages and access to affordable healthcare and childcare for postdocs. At least so that postdocs (who are generally ~30 years old) are capable of building their life (i.e. starting families, buying a house). Create money and positions that allow for advancement of postdoctoral associates within academic labs outside of tenure-track PI positions. Many labs would DEEPLY benefit from the expertise, continuation of knowledge, and training skills of a permanent scientist. There simply need to be more grants and resources for departments to begin to adopt such positions. Furthermore, allow more avenues for more departments themselves to hire scientific staff. Big data is a growing field and complication in neuroscience that few departments are equipped to manage. Many postdocs have the expertise and content knowledge to potential serve as a huge asset as a staff data scientist, data engineer, or statistical consult.

Proven or promising external resources or approaches

One approach that industry takes is paying a reasonable wage. Create avenues for internal advancement. Open up the flexibility of academic positions as a whole. There is very much an impression (if not a stark reality) that once you leave an academic position, you will likely not be able to return. This unnecessarily cuts academic science off from the research done in pharmaceutical companies, biotech companies, and startups. Encourage PhD students to pursue internships. Recruit postdocs and tenure-track positions from industry. But mostly just pay us a reasonable wage.

Response 1168

Perspectives on the postdoc roles and responsibilities

The postdoctoral position, in my view, is one that allows for additional training and experience in the desired field. I view it as a way to enhance my already specialized technical and professional skills.

Fundamental issues and challenges

I believe the most Fundamental issues and challenges are related to being underpayed and over-worked regarding hours put in and general expectations. Most pay for postdoctoral trainees does not cover cost of living for the area and does not keep pace with rise of inflation. I think there is also a tendency to view postdocs as cheap labor and this leads to exploitation. When there are environments that discourage the use of annual and sick leave due to the demands placed on the postdoc—this is inherently inequitable and leads to burnout and premature exits from the field.

Existing NIH policies, programs, or resources

Creating direct routes from postdoctoral to faculty positions for more than just research-focused positions.

Proven or promising external resources or approaches

Yalcin, Martinez-Corral, & Chugh (2023). Retaining postdocs by recognizing their worth, Nature Biotechnology, 41, 296-298

Response 1169

Perspectives on the postdoc roles and responsibilities

As a current postdoc, the postdoctoral position is an opportunity to gain additional skills that will be essential in my future career as an independent researcher at an academic institution. This time is also essential for obtaining publications and grant-writing skills.

Fundamental issues and challenges

The number 1 issue and challenge that inhibits recruitment, retention, and quality of life of postdoctoral trainees in academic research is compensation. The NIH salary range for starting postdocs is not nearly enough. As someone who recently started a postdoc position, I was the only person in my predoctoral cohort (group of 7) who went into a postdoc position. The others went straight into jobs (industry and academia)—and the reason for this was salary. The cost of living has exponentially increased over the past several years while the NIH postdoc salary ranges have remained stagnant. If you are wanting to recruit (and retain) more individuals into postdoc positions, the salary needs to be competitive.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

Again, a salary increase for postdocs in academia would address almost all of components (recruitment, environment, job satisfaction). It is time to change the atmosphere of continuing education and training and provide those who choose to go into it with adequate compensation.

Response 1170

Perspectives on the postdoc roles and responsibilities

These are not trainees. Postdocs are the driving force of experimental progress but have been shackled by the term trainee for too long

Fundamental issues and challenges

Salary salary salary! NIH has shown no understanding of the cost of living. Industry has capitalized on this extremely effectively

Existing NIH policies, programs, or resources

Stop limiting salary by through your antiquated salary standards. Postdocs don't need a "training ecosystem" as much as they need the ability to live and grow as a human being

Proven or promising external resources or approaches

Look at every industry salary standard and act accordingly

Response 1171

Perspectives on the postdoc roles and responsibilities

Important stepping stone for networking, learning additional research skills, more publishing experience

Fundamental issues and challenges

Same workload/caseload as full time employees for 1/3 the pay

Existing NIH policies, programs, or resources

Increased pay to mimic true organizational value

Proven or promising external resources or approaches

No response

Response 1172

Perspectives on the postdoc roles and responsibilities

Postdoctoral Fellowship to me is a stepping stone to doing impactful research and science. It is an unofficial full-time job to get an actual full-time job (faculty).

Fundamental issues and challenges

In light of the current postdoc environment, postdocs are overworked with little or no compensation. Training of postdocs aren't well executed and mainly depends on which Postdoctoral training programs they are in as well as their respective lab.

Postdocs are becoming extinct due to poor payscales compared to industry jobs. Industry jobs offer better working conditions and pay. With the amount of work I do as a postdoc in the biomedical research area, payment is absolutely garbage. This extends further for postdocs who have families to feed and who are non-citizens.

Existing NIH policies, programs, or resources

There should be a structure for all postdocs to follow, as well as their respective PIs. A training system where postdocs must attend courses and workshops for career development and this should already be paid for by the institution, not the PI themselves. PIs are already struggling to get funding.

Create a funding pool for Postdoctoral Associations. Current Postdoc Associations struggle to get proper financial compensation to conduct postdoc related events. This shouldn't be the case. The main driving force of Postdoc Associations are volunteer postdocs—quality of events depends on their time and well being. Postdod volunteers would have finished their program by the time they receive notifications and approval of funding for their events.This issue leads to Postdoc Associations being neglected with very low postdoc participation. Postdoc associations being the only bridge to connect our postdocs to the executives of the institution, is broken.

Proven or promising external resources or approaches

Postdoc/research strikes across the US is a promising approach to getting NIH to fully understand what the postdocs are going through. Science will die without postdocs.

Response 1173

Perspectives on the postdoc roles and responsibilities

Supposed to be more independent than during a PhD. Should theoretically be a pathway towards academia.

Fundamental issues and challenges

Money and time.

Post docs work an inordinate amount of hours, yet the pay does not reflect that. It simply baffles me how I continuously hear about a 'postdoc shortage' yet the thought of increasing postdoc pay is somehow blasphemy. Or PIs start making excuses about why they cant do it, or how expensive postdocs already are because 'I have to pay others benefits, so *really* they cost twice as much".

No. For the amount of hours postdocs work, and the implicit assumption that they should also be working evenings and weekends, the pay does not come close to making it enticing. Why should I choose to pursue a postdoc, work 60-80 hours per week, for little money, in a toxic environment, with few job prospects? There is nothing enticing about it.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

Look to industry—that is your main competition .What does industry pay its PhDs? What is the lifestyle in industry that attracts people to it? This isn't complicated, you just refuse to do it and make excuses about why you can't

Response 1174

Perspectives on the postdoc roles and responsibilities

Postdoc training is required for only foreign nationals who needs exposure to new technology, skills and culture

Fundamental issues and challenges

Immigration is a major issue in USA for postdocs. When they have PhD, they are eligible to apply for EB1. But EB1 standards were increased by USCIS. Even for H1B visa processing times are horrible by USCIS. Postdocs get very low salaries throughout USA, they cannot live with their families. Some supervisors are not willing to support their postdocs for their immigration. Most of the postdocs are working at least 8-12 h daily without break. After considering all these factors, people are moving to other countries where immigration is not a big hurdle for them. Many Asians are struggling with immigration compared to rest of the world, due to specials quotas for them. For example a person from Pakistan will get his green card in 6 months, because he will apply for EB2 where the standards are very low. For Asians EB2 VISA dates are in 2012 as of 2023. So they need to wait for 10 years with their low income. They have only one choice that is EB1. They have to hire an attorney and pay them around 10K for filing the petition, which is not 100% success guaranteed. In conclusion a person from Asia with 500 citations and 100s of publication is not given priority when compare with a person from rest of the world with 50 citations and 5 publications. I am sure there will be no postdoc from Asian countries soon in USA.

Existing NIH policies, programs, or resources

Postdocs are not aware of the salaries allocated to them in NIH grants. Some supervisors are misusing this, and appointing 2 people by dividing one salary from NIH. We are not sure how they manage.

Proven or promising external resources or approaches

NIH should ask salary statements from postdocs to avoid misuse of funds. Also USCIS need to give same priority to all foreign nationals based on their profile not based on their birth country.

Response 1175

Perspectives on the postdoc roles and responsibilities

The postdoctoral position should provide the scientist with the liberty to explore the topics that will constitute her/his future field of research. Should provide TRAINING and RESOURCES to pursue that independent career.

In my institution (Moffittt Cancer Center), the training is inexistent and the opportunities for growing, scarce. In the real academic world, a postdoc have the role of project manager, grant writer, manuscript writer, mentor (for PhD students and undergrad students), sometimes lab technician (depending on the resources of the laboratory), community manager of the lab.etc.

If, as me, you are foreign, you have the additional handicap of not being able to easily change your position within the institution or between institutions. That means that if you have any personal or professional issue the probability to foster your career is dramatically impaired.

Fundamental issues and challenges

Salary. How can a Postdoc, with such a education level, earn only 50k as an entry level? Specially when jobs with less qualification have entry level salaries much higher. Economics impact us as well. If cost of live rises 30% and our salary remain the same.well.you can do the math.

Benefits. That changes between centers, but the benefits are highly different comparing the Staff members and postdocs at the same institution, even with a higher level of education we still have poorer benefits. That is exacerbated if you are foreign.

Working hours. I wonder why a Staff Scientist at an institution have a cap in the 40 hours of work/week but a Postdoc have no control in the working hours. Nobody have a control of the hours we work, neither cares if we work on weekends, National Holidays, etc. Just to say it plain, some Postdocs are consider as slaves for some PIs. Furthermore, if you come from India or China, what it is expected from you is to endlessly produce with no control or relief.

Lack of progression. Because the scientific system is a funnel in which we loose professionals as we progress through the system, many Postdocs will never reach a Faculty position, which is supposed to be the primary goal of the Postdoc. Because of that, many Postdoc just find a way outside academia, and that is increased when we add the high salary, better benefits and more flexible working schedule outside academia.

Immigration status. Why can I work in the US as a Postdoc under a J-1 VISA and still not be considered a Resident? How can I remain attached to academia in a system that treat and see me as a foreigner even if I constantly make great contributions to the wellness of the country?

Existing NIH policies, programs, or resources

Equity programs that pursue the equal rights between Postdocs from any nationality.

Ease of transition from foreign researcher to U.S Resident.

Funding resources for Postdocs.

Guidance during the transition from Postdoc to Principal Investigator.

NIH should obligate any institution having Postdocs to provide them with QUALITY TRAINING.

Rise the NIH Standards for Payrates so Postdocs positions can be more attractive to people, that way preventing their leaving for industry.

Create more programs and policies for mental health and wellness in the Postdoctoral communities.

COME AND TALK WITH US. I am not meaning doing just a survey. COME TO THE CENTER AND TALK WITH POSTDOCS. Do you know that, in Moffitt Cancer Center, we have no freedom of speech and cannot express our feelings about the conditions of the postdocs in a public forum, otherwise we will face professional consequences? Well, that is something the system may need to regulate at some point, and you can detect it if you talk with the people at the institutions.

Proven or promising external resources or approaches

I currently have no contracted information to answer this question.

Response 1176

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

The salary postdocs receive is below what they truly deserve and it is not justified in any ways to the amount of work (energy and time) they put in. Therefore, I believe less and less PhD graduate are motivated to pursue their career as postdocs and the one who are already postdocs, such as myself, are struggling with their everyday life.

Existing NIH policies, programs, or resources

Salary increase

Proven or promising external resources or approaches

No response

Response 1177

Perspectives on the postdoc roles and responsibilities

As a current postdoc I find the position interesting, motivating and cognitive challenging in a positive way. However, the pay is way too low. I live in the Boston area and earn $55,000/year. I have to pay $10,000-20,000/year out of my own pocket savings just to be here.

Fundamental issues and challenges

I live in the Boston area and earn $55,000/year. I have to pay $10,000-20,000/year out of my own pocket savings just to be here.

Existing NIH policies, programs, or resources

A salary of $80,000/year is not very high, but would be enough to sustain a normal living as a postdoc

Proven or promising external resources or approaches

Higher salary

Response 1178

Perspectives on the postdoc roles and responsibilities

A postdoc position is an opportunity for more training, usually in a different field than one’s graduate research. Emphasis is on publishing manuscripts and obtaining independent funding as a step towards becoming an independent investigator/faculty.

Fundamental issues and challenges

Pay!!! Many high-impact labs are in very expensive cities and postdoc (and grad student) stipends have not remotely kept up with inflation or the rising cost of living around the country. The NIH has to increase its minimums and increase R01 budgets so PIs can pay their people a livable wage. Postdocs are highly trained and skilled scientists but are not compensated as such. Many people are skipping the postdoc because you can make so much more money in industry without post doc experience than staying in academia. Work-life balance is also allegedly better in industry without constant grant writing/struggling for funding and publish-or-perish cultures. It is also taking longer and longer for postdocs to find faculty positions and stay in academia because current faculty don’t retire and there are few job openings and limited space for new faculty positions.

Existing NIH policies, programs, or resources

The NIH has to increase its minimums and increase R01 budgets so PIs can pay their people a livable wage.

Proven or promising external resources or approaches

Pay attention to graduate student and postdoc movements and strikes around the country. They are telling you what they need.

Response 1179

Perspectives on the postdoc roles and responsibilities

Enhance skills to transition to independent researcher in academics.

Fundamental issues and challenges

Lack of ability of PIs to compete with industry salary—we don't get enough funding from NIH for this.

Industry has become the golden egg for career choice and many feel an academic postdoc is not needed anymore—some of this is that postdocs see the academic life and don't know much about the industry life so it automatically seems better.

Existing NIH policies, programs, or resources

More salary support for postdocs.

Proven or promising external resources or approaches

No response

Response 1180

Perspectives on the postdoc roles and responsibilities

It is a gray area to prepare me for future career, I am neither a faculty nor a graduate student. I also have a chance to pursue specific field of study that I really like it.

Fundamental issues and challenges

Financial problem is the main issue. Regarding inflation, it is very hard to survive with postdoc salary. The second Issue is job security. It is very unstable position, and you cannot rely on as a job.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1181

Perspectives on the postdoc roles and responsibilities

A postdoctoral is equivalent to a residency for clinical training, during which a junior scientist is trained to be an independent scientist. A postdoc has to be given all tools (academic, research, and administration) to succeed and further promote the eagerness to become an accomplished and useful scientist. Established scientists and faculty at different levels must assume their responsibilities vis-Ã -vis postdocs to ensure adequate training and a healthy research succession

Fundamental issues and challenges

Limited funds to ensure good income for postdocs is a big hurdle toward recruiting US postdocs. Also, a lack of an adequate retirement program for established scientists prevents these postdocs from occupying positions in research centers (hospitals, universities, or private research centers), and this discourages students from pursuing a research career.

Existing NIH policies, programs, or resources

- The $500,000 cap
- The modular grant
- Low pay line range for every Study Section, are all among the big hurdles that indirectly negatively impact the disinterest of postdocs and graduate students in pursuing research career.

Proven or promising external resources or approaches

Establish a competitive funding program specific to recruiting US postdocs from US universities.

Increase the pay line for every study section, and eliminate modular grants. Federal and State officials have to increase substantially funds for research (science and medical)

Response 1182

Perspectives on the postdoc roles and responsibilities

I see the role of the postdoc as twofold. First, postdocs are hired to carry out the research programs of principal investigators. We are highly valuable workers because we have the depth of knowledge and skill to not only progress the research for which funding has been secured, but also to troubleshoot and come up with new experiments that will enhance the studies. Second, postdocs receive training from their mentors on how to become independent investigators. This means that our mentors should help us identify grant opportunities and ensure we get practice in how to write successful grants. We should also be encouraged to develop independent projects that are distinct from the PI's. Postdoc positions should be started with the goal of independence in mind, to avoid a protracted and ambiguous training period.

Fundamental issues and challenges

These days, postdoc salaries are extremely low and cannot compete with cost of living and inflation. The NIH minimum postdoc salaries are nationwide standards and universities in expensive areas need to supplement the salaries so that postdocs can make ends meet. Instead, many universities offer the NIH minimum in cities like New York and Boston, which means postdocs must live with near-poverty income levels. Salaries need to be high enough so that postdocs can live comfortably. There seems to be an attitude that postdocs don't need to be paid that much because they are "trainees," and should be doing research because they are passionate about it, not for the money. Even if they are still undergoing training, postdocs still deserve to live comfortably. Furthermore, the "training" postdocs are supposedly receiving is often ambiguous. Many principal investigators are not actually invested in helping them develop independent careers. This is especially the case with international postdocs, whom many PIs don't even know how to help. They end up just being cheap labor for them, which is very exploitative. Along those same lines, many mentors are abusive and promote work environments that are overly competitive and reward over-working, or they simply ignore issues of toxicity in the workplace.

Existing NIH policies, programs, or resources

Currently, postdocs are punished, rather than rewarded, for obtaining NIH fellowships. I secured an F32 last year and, as a result, became an "independent contractor" at my university, meaning I don't get taxes taken out of my paycheck and I have lost my retirement benefits, and the F32 does not include health insurance, so the money for that has to come from my PI. I am missing out on a total of $18,000 in my retirement account. I am clearly still an employee at my university and hardly "independent," since I am still accountable to my PI. Why can't these NIH fellowships include fringe benefits and be awarded in a way that doesn't make us lose our status as university employees? Additionally, R01 grants need to have higher budgets to accommodate higher postdoc salaries. The NIH minimum salary must be increased.

Proven or promising external resources or approaches

No response

Response 1183

Perspectives on the postdoc roles and responsibilities

My postdoc training has been a great period of my career to get prepared to the next step: becoming a group leader. During this time I could do exciting science at a much faster pace and with much more independence. But I also developed essential skills like grant writing, leadership and mentoring skills.

Fundamental issues and challenges

- I think the biggest challenge when being a postdoc is the uncertainty of how long this stage is going to be and if we would get the permanent position that we ambitioned. It is not clear what you will need or when you are ready to transition and everyone has a different opinion, mostly based on their own experience. I also find very discouraging the concept of "fit". I have seen people with bad CVs getting PI position while people with good CVs had to go back to their home country or left academia for lack of opportunity. The "excuse" of fit is the way to hire based on personal biases and allow much more room to discrimination.
- Another important probelms are related with family life. Lack of affordable daycare system makes almost impossible to have kids during postdoc while trying to build a career. Sometimes, even if universities have daycare system, postdocs are not considered full employees and they don't have priority to get a spot. They need to find somewhere else and pay more money. This problem also applies to attending conferences: attending conferences during your postdoc is critical to establish your network, but it becomes extremely challenging if you have a kid.
- The lack of dual career plans during postdoc. While the two-body problem has been widely discussed in many editorials and it is a known problem/topic, no one talks about the difficulties of finding two jobs in a new city/state/country when you only hold a temporary position. Most universities and research institutes do not offer official help to deal with this circumstance.
- Lack of good benefits. Many universities and research institutes have worse conditions for postdocs than for the rest of employees: no retirement plan, no opportunity to choose between different health insurances.

Existing NIH policies, programs, or resources

Allowing international postdocs to apply to F32 and other mechanisms (diversity supplements etc) would make the US a much more attractive place to do a postdoc. The requirement should not be residence or citizenship but if you paid your taxes in the US the previous year.

I also think that the real lenght of a postdoc is between 6 years (at least in my field, neuroscience), which has increased, and this is not reflected in the time of ESI status.

Another shameful move from the NIH was not adding the extension because of COVID to the extension because of childbirth for K99 eligibility (at least for NINDS). As a consequence, mothers were allowed to have only one more cycle than the rest of the people. When I complained about this, they told me that they didn't want us to extend our postdoc with no need. I wish they understood that my postdoc was already extended because of my personal circumstances and I only needed the NIH to acknowledge that.

Proven or promising external resources or approaches

No response

Response 1184

Perspectives on the postdoc roles and responsibilities

I am very passionate about my job and I absolutely love science.

Fundamental issues and challenges

Our salary is too low and does not allow us to even live on our own. Research is stressful but that's fine—we love the adrenaline! However constantly worrying about money adds too much stress on top of it, and that becomes unhealthy!

Existing NIH policies, programs, or resources

Increasing the number of accessible grants to international/non-US postdocs

Proven or promising external resources or approaches

Response 1186

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

The postdoc period is viewed as a period to gain skills to move into an independent research position. In my personal opinion, the NIH and other funding institutions do not value nor consider within its policies doing a training overseas. Building a global academic community and retaining scientists with leadership skills that integrate a respect for cultural perspectives should have a higher priority in the United States for its own citizens. Academic institutes value bringing in academics from overseas but not sending their own candidates overseas. Moreover, if a scientist performs a position overseas and takes standard parental leaves at those Institutions the NIH policies for adding time to extend grant eligibility period restricts child birth to six months while an investigator who took more than this overseas does not get the true needed extension. I personally have found many grant application reviews, after returning from a time overseas, commenting on productivity when these are not taken into consideration.

Existing NIH policies, programs, or resources

The NIH policies do allow for extensions due to health but reviewers themselves seem to not take these into account when reviewing the candidate themselves. I have gotten many comments on productivity and ability to manage a lab. As a cancer researcher, who was diagnosed with cancer which delayed productivity it felt difficult to prove my worth to review boards after such an illness. When the truth is that my cancer made me more motivated and passionate about my career. I once asked for the ability to submit a K22 application a few days late because I had to have a last minute cancer surgery a few days before and was denied by the Program manager.

Proven or promising external resources or approaches

In Norway there was a system to help recruit more women and diverse leaders by offering positions and grants which were aimed at a slightly lower position (ie junior faculty versus full faculty or late stage postdoc versus junior faculty) in order to get more female and diverse researchers to apply. This was based on the scientific findings that women are less to apply for positions they feel that they do not fit the recommended skillset.

Response 1187

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

The salary for postdocs is far too low.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1188

Perspectives on the postdoc roles and responsibilities

I personally view a post-doc as position to develop my skills as an independent scientist and gain the ability to run my own research group as an investigator. It is an opportunity to establish my own research program by having greater ownership over my projects, expand my scientific network by attending conferences, begin applying for my own grants, and learn in a different environment than my PhD. I believe the postdoc is ideally suited for those interested in pursuing academic research, but others may find it valuable to become a group leader in industry or government.

Fundamental issues and challenges

I am currently a senior PhD student applying to postdoctoral fellowships in academia and intramurally at the NIH. I will include issues that have impacted my career path, as well as ones I have frequently heard from those who have chosen not to pursue a postdoc.

- Salaries for postdocs are too low compared to industry.
- While a postdoc was once seen as necessary to enter into many industry positions, there is a greater realization that a PhD alone is sufficient to enter industry. Time spent doing a postdoc may be better spent being at a company, allowing one to rise through the ranks by gaining more relevant skills to working in industry or biotech.
- Postdocs have become longer
- Increasingly, I think trainees realize that in order to get a faculty position, you must do a postdoc in a "famous" or highly established lab. So while the most established PIs will continue to get new postdocs, less famous labs (and especially early stage investigators) struggle to recruit postdocs, since the likelihood of publishing highly or winning grants as a postdoc is lower, and this is key for career advancement. Maybe early stage investigators could be allowed to offer a higher salary to prospective postdocs? Or more favorable grant paylines could be offered to postdocs applying from these labs?

Existing NIH policies, programs, or resources

- Salaries for postdocs need to be increased. Raises that do not meet the CPI threshold for inflation are not raises, they are a functional decrease in pay. It is painfully obvious how the earning power of postdocs has been diminished as inflation has increased.
- Differences in postdoc pay between cities are rarely commensurate with cost-of-living differences. This creates problems for those in expensive areas. While this should be addressed, I actually think it's a benefit that a postdoc in a low cost-of-living area gets paid about the same as a postdoc in a high cost-of-living area. This offers a nice incentive for postdocs to go to institutions in more affordable areas. There are good labs in non-coastal elite cities that need to be able to lure postdocs with the promise of a better quality of life.
- Being awarded a fellowship (such as F32/K99) should not be a financial punishment to postdocs. I have heard of postdocs receiving a lower salary, losing health insurance, or losing other benefits (retirement, etc) because they have won a fellowship award and no longer get these from their institution. Postdocs should not have to sacrifice this to accept an award that advances their careers. My vague understanding is that individual institutions may have more power over this than the NIH, but perhaps the NIH can stipulate as part of the award that the institution is required to continue giving these benefits to the trainee.
- Some incentives perversely encourage one to stay in a PhD longer, rather than begin a postdoc. I have advised to delay my defense in order not to trigger the Early Stage Investigator clock too early. Some benefits such as insurance, childcare, subsidized housing are better for PhD students than for postdocs.
- More opportunities for retirement savings/benefits from NIH-funded postdoc positions.

Proven or promising external resources or approaches

No response

Response 1189

Perspectives on the postdoc roles and responsibilities

A postdoc is a necessary position for those wishing to develop independent research projects but is not required for those wanting to go into industry or serve as a scientist (academia or industry).

Fundamental issues and challenges

Postdocs are not official employees of universities = worse benefits. Postdocs salaries have increased tremendously but are still not comparable to industry. For those not wanting to pursue an independent PI position, there is little incentive or benefit.

Existing NIH policies, programs, or resources

Dedicate funding for graduate students wanting to transition. T32s are good but limited to 3 years (generally used during grad school). The F99/K00 looks like a good program. Will still lack benefits of being an official university employee though.

Proven or promising external resources or approaches

Academic culture beyond the postdoc position (i.e. scientist positions) are a strong incentive but postdocs have to committee to 5 years before reaching that level. Salary at both postdoc and scientist level in academia still below industry as well. Leveraging the culture of academia might be beneficial postdocs need more commitment early on.

Response 1190

Perspectives on the postdoc roles and responsibilities

Additional training to prepare the postdoc for a scientific position

Expect them to help train the grad students, to produce high quality data, to publish, and to write for fellowships and give talks at national/international meetings—these things all add to their training in order to prepare them for a career in science.

Fundamental issues and challenges

Students are now going directly into industry—which pays much better. One of the problems is the length of time graduate school and then postdoctoral fellowships now take—in part due to the high demands for publishing in high profile journals (which requires a significant amount of data that cannot be generated in just a couple of years). Postdocs have a hard time affording housing and a family—and they are at an age when they should be starting their families. Thus they often feel they have to choose between academic science and affording to start a family.

Existing NIH policies, programs, or resources

If we want to increase pay—we need to think about increasing the modular budget which has been stagnant since 1999. We also should raise stipends. Of course—we have to balance that with the risk of reducing the # of awards—but I think it needs to be done.

Proven or promising external resources or approaches

Postdoc offices that have training are helpful—creating a strong community of postdocs is helpful. Having child care (that is affordable) on site at academic institutions is a great help—as well as having subsidized housing. Helping young mothers to have places to nurse on campus—and to be able to take their children to academic meetings also will help.

Response 1191

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

The annual salary is too low for a good quality of life. With a spouse and 2 young kids, I struggle to make ends meet. And the salary is absolutely not competitive with non-academic positions at equivalent level of expertise.

The financial status of postdoctoral fellows is unfair. The NIH needs to advocate to the government to change how fellows are taxed and how they pay their insurance premiums. And in the meantime, they should increase salaries to make the fellowship financially appealing. An award should not be so just based on CV prestige. Currently, it is very often NOT financially advantageous to accept an F32 fellowship because of the huge increases in health insurance premiums (from university employee status to self-employed) that also turn out to be not tax-deductible (in contrast to postdoctoral university employee or normal self-employed people). It’s an outrageous double-whammy. Postdoctoral fellows should not be considered self-employed and the NIH should incentivize universities to support them instead of the opposite.

Also, more advising should be provided to help postdocs navigate the financial changes and the rules attached to the grant. Currently, it’s a huge headache, and university administrators are not trained and generally don’t have the time to teach postdocs. A lot of time that could be used for research is lost to figure out financial issues.

Existing NIH policies, programs, or resources

The $2500 Childcare cost allowance: it’s good that it exists, it’s very appreciated but given the actual costs of childcare nowadays, it’s just a drop in the sea and should be increased significantly.

Relatedly, the authorized expenses from the $11,000 institutional allowance should be expended. It would make sense to allow childcare costs to be paid with this allowance because it is actually hard to use it all for what’s currently authorized (e.g. conferences, workshops, summer courses) when you have young kids to take care of. For instance, in my application I put in the idea to attend a 4-weeks MBL course on computational neuroscience and another one on microscopy, but in practice it’ll be hard or impossible as the MBL only offers childcare options for children aged 4 or older (which is already better than most conferences and professional development events). Moreover, family travel expenses should be allowed

expenses: preventing immediate family (spouse and kids) to come during professional development events limits what fellows can do for their training, and likely hinders women more than men. All the professional development ecosystem in academia is still built on the premise that you are a single person or that you can afford to leave your family behind. This needs to change, and the NIH is in a strong position to force that change and incentivize training institutions to be more family-friendly and provide free or low-cost childcare if they want to be inclusive.

Proven or promising external resources or approaches

No response

Response 1192

Perspectives on the postdoc roles and responsibilities

Post-doc time should be when a person can gain additional skills and figure out the direction of their program of research. Gaining teaching experience is helpful for those pursuing careers in academia.

Fundamental issues and challenges

1) Post-doc salary—Not adjustable for cost of living in high cost places. After trying to live on a doctoral stipend, it's hard for many prospective recruits to only see a 30% increase in salary to the $50K range. Schools of Medicine grossly subsidize their post-doc salaries because they can draw from GME training funds. This leaves the rest of the health professions lagging and makes it more difficult to recruit diverse students.
2) Cost of child care—For persons with children, they cannot afford to take a post-doc job because of childcare costs. The model of relying on one's spouse for the majority of income (which most will have done already for 4 years of PhD study at least), strains partnerships for an additional two years and is gender biased. I had a highly qualified post-doc candidate turn down a position because of childcare costs.
3) On-site requirement—I've had very good experiences with remote post-doc mentoring. For people with children, and especially women, this model can work really well. The person came onsite every other week for a few days and we had intensive working sessions and then other work was completed remotely. The cost of staying in a hotel for 2 night every other week and flying to where we are located was cheaper than renting an apartment.
4) Less mobility—We see less mobility in our PhD students as they tend to be in their late 20s, early 30s and more settled than someone straight out of university. That means they are limited to post-docs within the area since they cannot move due to personal reasons.

Existing NIH policies, programs, or resources

1) Have cost of living salary adjustments be allowed based on post-doc location.
2) Create a monthly childcare allowance that gets paid directly to a provider.

Proven or promising external resources or approaches

Create remote post-doc options with some onsite time requirements.

Response 1193

Perspectives on the postdoc roles and responsibilities

The postdoctoral position is a position in which the researcher begins to become independent and developing their own aims and abilities to transition into a leadership position. They should be involved in the mentoring culture of the lab and start to fulfill some of the duties a PI is allocated—e.g. reviewing papers—and establishing their name and science both domestically and abroad.

Fundamental issues and challenges

Fundamental to this issue is right in the posing of this prompt—how we reference postdoctoral researchers as "fellows," "researchers," or—as is phrased here—"trainees" is key. Seeing them as trainees after extensive training is why we lose good future leaders in the academic sphere to industry. Because they are

viewed as trainees, they are paid as such. Grad students generally sacrifice 5-7 years of income that is only barely sustainable to have fairly marginal bumps in pay upon advancement to the postdoctoral position where, again, they are not making what peers (and even those with less extensive training) are making. NIH guidelines that give the salaries postdoctoral fellows can receive are used as 'rules' at academic institutions to shift the blame to the NIH when low-balling the worth of the researcher. Capping the salaries that NIH grants can give also compounds this issue as even if PI's could/would give higher salaries, the NIH cuts them off at the knees.

Existing NIH policies, programs, or resources

No response

Response 1194

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

No response

Existing NIH policies, programs, or resources

R mechanism grants should include a funded postdoctoral position, at the institutions mandated rate (if different than NIH), in addition to the existing budgetary limits. This would provide assurance of adequate funds for postdoctoral training are available, while reducing the currently ever increasing pressure on research budgets. For example, an R21 and R01 budget could include up to 6 months and 12 months supplemental annual postdoc effort, respectively. Additionally, allowing the investigator to determine whether the effort should be assigned to a single trainee or split between multiple trainees, to ensure best alignment with project needs.

Proven or promising external resources or approaches

No response

Response 1195

Perspectives on the postdoc roles and responsibilities

I view the role of postdoc as a junior investigator, someone who can plan and mange scientific research project as well as lower degree staff. The difference I see with senior investigators is that we are still gathering experience and potentially choosing our research field.

It is stunningly accepted for postdoc researchers to be underpaid, overworked and belittled; all of this with the NIH's duplicity. The research a postdoc does is just a valuable as the one done by a associate professor; as it is actually not the heads of the labs doing the research.

Fundamental issues and challenges

Salary

Belittlement ("trainees")

Work/life balance

Working conditions

Existing NIH policies, programs, or resources

I lost my previous postdoc position for reporting animal cruelty, fraud, scientific fraud, harassment, misconduct and dangerous behavior; the NIH refused to act and to this day still funds the said team and university.

Postdoctoral researchers should not be at risk of losing their job for abiding to the law and ethical behavior.

Proven or promising external resources or approaches

Stop being duplicit of crimes, start respecting people.

Response 1196

Perspectives on the postdoc roles and responsibilities

For me, postdoctorate is a transition between the end of my doctoral career and work, which means that I should try my best to find my research interests and improve my personal skills during this period.

Fundamental issues and challenges

Uncertainty about the future, research pressure and low income level

Existing NIH policies, programs, or resources

Expand post-doctoral jobs and improve post-doctoral treatment

Proven or promising external resources or approaches

Expand post-doctoral jobs and improve post-doctoral treatment

Response 1197

Perspectives on the postdoc roles and responsibilities

I see my postdoc position as training for independence. I should broaden my set of skills to be able to write a successful K99/R00 grant and open my own lab

Fundamental issues and challenges

I'm heavily underpaid. I understand a postdoc career followed by a PI position requires time and determination. I don't mind working many hours (I do way more than 40hrs per week, also working on weekends). I like the freedom and dynamics of my job. However, the plumber without a college degree in our building has a higher salary than I do. I work in a non-profit foundation—my grants bring all the money to support HR and maintenance crew, but at the same time I'm not paid relevant to my education! I can't afford my own apartment/house. I need to rent and I face rent termination and changing prices all the time. I don't have stability, I'm not able to create a family in this environment

Existing NIH policies, programs, or resources

1) We should work on higher salaries for the postdocs
2) The grant/funding options for immigrant/visa holders are limited. The lack of those opportunities impedes my training and progress

Proven or promising external resources or approaches

As a postdoc, I struggle with job satisfaction. I like my work, but at the same time, I feel guilty that I should move to the industry and start earning more money to support my family. Even small efforts proving I'm appreciated in my workplace could change my feelings, like covered medical insurance.

Response 1198

Perspectives on the postdoc roles and responsibilities

I view the academic postdoc as a job in scientific research. Perhaps the purest and most hands-on form of scientific research, but the key operative word here is "job."

Fundamental issues and challenges

This summarized my thoughts very well:

https://www.nature.com/articles/s41587-023-01656-4

Existing NIH policies, programs, or resources

Again: https://www.nature.com/articles/s41587-023-01656-4

For a PI, a postdoc should be expensive and rare. We have to phase out this whole system where postdocs are the main driver of the most important research that a lab does. This might mean lowering expectations a little bit in terms of preliminary data for grants and/or rewarding PIs who commit to actual training at the (slight) expense of their research.

Proven or promising external resources or approaches

No response

Response 1199

Perspectives on the postdoc roles and responsibilities

Postdoc Goals / Personal Growth Opportunities:

- Learn new research areas and technical skills
- Improve confidence and speed with academic writing
- Submit independent proposals. Build an academic brand and establish scientific independence.
- Build a diverse network of collaborators

Postdoc responsibilities and contributions:

- Diversify expertise of a research group, improving the group's capability and impact.
- Generating new research ideas, collaborations, and questions.
- Collecting data and preparing results for publication
- Mentoring junior researchers, particularly MS and PhD students.

Fundamental issues and challenges

Low salary, poor support for family and other needs (childcare, transportation, housing, etc.), frequent re-location, short-term contracts (1 year renewable) are not practical for someone with family responsibility, competition amongst postdocs for resources, lack of career coaching. Stress and mental health challenges associated with long-term career uncertainty.

Existing NIH policies, programs, or resources

Broadly, I would like to see greater consolidation of postdoc professional development resources and more funding that is given to the postdoc instead of the faculty mentor (to facilitate more rapid transition to independence). I would love to see an expansion of the F32 and K99 programs. I would like to see international scholars who intend to become US permanent residents to become F32 eligible. Would love to see more programs that give award to early stage postdocs (1st or 2nd year) that include bridge funds for independence. Expansion of MOSAIC and similar programs for DEI action. I would also like to see centralized career resources at the NIH level that can be provided virtually to all postdocs so that individual institutions do not have to generate them redundantly. I would also like to see mandatory FMLA availability / insurance for NIH funded postdocs.

Proven or promising external resources or approaches

N/A, this is a bit outside of my expertise.

Response 1200

Perspectives on the postdoc roles and responsibilities

The academic postdoctoral position, in my eyes, represents a phase of training wherein a scientist can exercise their ability to think and work independently on a project--to take their work from conception to the point of sharing it with the greater research community via publication--within the supportive environment of an established mentor's laboratory, as a means of demonstrating their readiness to start

their own academic laboratory, or to join an academic laboratory as a staff scientist, or to decide to leave academia for other reasons, depending on their own personal goals.

Fundamental issues and challenges

This issue is singular. Postdocs are underpaid for the staggering amount of training and expertise we have established. Research is a labor of love. Many stay the course because of this, but struggle financially as we struggle professionally. Some on this career path are fortunate to have a robust support system: dual-income or other financial support, a supportive family structure, or a supportive mentor. But consider the common alternative, such as my own experience: I earned an undergrad biochemistry degree in my mid-twenties on loans and credit cards, then worked as a technician to gain sufficient laboratory experience for graduate school while making minimum payments on these debts, started graduate school in [redacted for anonymity] --arguably the most expensive city in the world--where my stipend allowed me to survive literally down to the dollar each month sustaining these debts, and finally became an [redacted for anonymity] postdoc, where, considering the increased rent from losing my subsidized graduate school apartment, my salary hardly improved the situation at all. I have over a decade of training, and as a 37-year-old postdoc, I barely earn enough to pay the debts I've accrued. I have no savings, no safety net, no guarantee that my scientific success will even result in the establishment of my own laboratory. Starting a family would be impossible. For those who've endured this system, the appeal of leaving it to receive a fair wage and improved quality of life is obvious. I should note that this bleak perspective is not an underdog's. I'm a white man with an Ivy League PhD and accolades to go with it. I'm privileged. I cannot imagine the daunting endeavor this path represents to someone from a less privileged background. Postdocs are leaving academia because this system is broken and increasingly unappealing to anyone aware of what they're getting into.

Existing NIH policies, programs, or resources

Any modifications that enable higher salaries--more reasonable living wages--and greater benefits packages should be the focus. Postdocs will stay in academia if they can survive financially in academia. Since salaries across virtually all academic institutions are limited by NIH pay guidelines, even extremely well-funded labs are not allowed to pay postdocs a salary above these frankly insulting rates.

Proven or promising external resources or approaches

Our recruitment, training, working environments, mentors, and satisfaction with the job itself are not the problem. We are simply not paid enough to survive.

Response 1201

Perspectives on the postdoc roles and responsibilities

My post doctoral fellowship has been a time to lay a foundation in my research specialty, without the pressures and responsibilities of being faculty. I can completely immerse myself in the exploration of my topic.

Fundamental issues and challenges

I have felt extremely well supported in my post doctoral fellowship through my school and especially my mentor. Some of my post doctoral colleagues are less supported in that they are work horses for their mentors and do not have the time or resources to devote to their individual research interests, or they have mentors who are protective of their work and reluctant to share responsibilities.

Existing NIH policies, programs, or resources

More networking amongst post doctoral fellows would be helpful, thanks for asking!

Proven or promising external resources or approaches

No response

Response 1202

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

Not enough pay.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1203

Perspectives on the postdoc roles and responsibilities

Postdocs are leading scientists in general, because they develop, run and manage their projects. We already have the expertise and many of us a few years of experience in a certain field, so we exactly know how to design an experiment, how to troubleshoot (which is 85% of times), present the data and write a publication at the end. Many of us apply for grants and get sponsored this way, so we're "self sufficient". I think that experienced postdocs are equal to research scientists and should be considered as such.

Fundamental issues and challenges

Compensation is the biggest and main issue. People with a PhD, several years of experience, great management and presentation skills are payed less than 60K a year. As a transition job for a short period of time after graduating or an adventure in a different country, it's nice, but as an actual job that should pay the bills, it's a disaster. That's why people, especially the very well skilled, prefer to get a job in the industry where their salaries will be significantly higher.

A big problem are also toxic PIs that try to almost enslave postdocs. There're some people struggling with mental health because of a bullying PI. It's a serious matter that the departments try to overlook because of the PI's reputation. I think that PIs should be evaluated more carefully and not be allowed to hire trainees if they're known to treat them poorly.

Existing NIH policies, programs, or resources

More "smaller" grants that people could apply for.

Evaluation of PIs.

Extended paid parental leave and financial aid for daycares/schools

Proven or promising external resources or approaches

No response

Response 1204

Perspectives on the postdoc roles and responsibilities

The view I have on my current, postdoc, position is bleak. While I am thrilled with the work that I do and the team/lab I do it with, the fact still stands that we are overqualified, undervalued and in a unique position which leads us to "compete" for roles (e.g. faculty) that are few and far between. The only "light" I see at the end of the tunnel is leaving academia, and I am fortunate to have a PI who understands this and supports my move into biotech/industry roles.

Fundamental issues and challenges

The quality of life that postdoctoral trainees have is pretty sad, which certainly leads to the challenge of retention—why would specialized scientist continue to contribute to a system that is both archaic and unappreciative of their work?

Existing NIH policies, programs, or resources

Increase pay significantly. For perspective, the NIH cap on salary for postdoctoral trainees is around 60,000, while many of the roles in industry or biotech start at 120,000 (and go up to 300,000). Keep in

mind, these roles require the same (sometimes less) amount of skill and hourly commitment as postdoc positions, thus making it a no-brainer that people should leave the system.

Proven or promising external resources or approaches

No response

Response 1205

Perspectives on the postdoc roles and responsibilities

- Postdocs remain the key for high quality science in the US academic system
- While lobbying for more salary and benefits for postdocs is absolutely the right thing to do, the establishment of "contracts" etc incresingly conveys the feeling that postdoc training is a "job", which is not.
- The fact that Institutions strictly limit the numbers of professional and PhD students that they can admit but not of postdocs (this is because Institutional -not PI-based—investment in postdocs is generally minimal) contributes to the fading awareness of the training nature of the postdoc position
- Institution branding remains the key attractor especially for foreign postdocs (everybody wants to have "famous place-trained" written on their CV). This leads to a few Institutions attracting all the postdocs in the absence of proven measures that the postdoc experience and quality of life is better at such Institutions.

Fundamental issues and challenges

- PhD graduates especially domestic ones do not find the traditional academic PI career attractive anymore so they often see their PI labs as just a stepping stone toward a career better than their PIs' one (industry, consultantship, entrepreneurship, etc).
- Postdoc salaries and benefits are ever increasing but still do not guarantee a decent lifestyle in many parts of the US to these people who are often in their 30s and have families to support
- T32 funding is competitive and Institutional support is factored (albeit in a non binding non cost sharing way) in the competition but funding of postdocs from grants is not subordinated to any specific level of Institutional support
- Further increases in salaries and benefits is limited by the fact that postdocs are 100% supported by PI grant budgets which are limited in size and duration
- Almost no mechanism from NIH exists to support the next steps for postdocs who do not want to become PIs but stay in academia. K awards are mostly only for residents or citizens. No Institutional commitment to a certain # of years of employment is required in order to post senior training positions.
- No mechanism exists to reward persistence in the postdoc position for a minimum amount of time rather than quickly transitioning into a more desirable non academic position
- IMPORTANT: no mechanism exists for the NIH to collect and publish surveys of postdoc quality of life at various Institutions despite the fact that most postdocs are entirely paid on NIH funds

Existing NIH policies, programs, or resources

- Requesting a cash buy-in from the Institution (not the PI) for every postdoc position that is budgeted on grants or in order to apply for T32 grants is the key step
- Requesting that Institutions cap the number of postdocs and provide specific benefits (housing, child care) to postdocs at their (not the PI) expense as a condition to get postdocs paid by grants or receiving T32 funding
- Requesting that Institutions with high postdoc numbers reserve a certain # of regular jobs to internally trained postdocs
- Creating funding mechanisms for Institutions to have senior scientists (similar to T32 but not for training, e.g. senior scientist pool grants)
- Requesting as a condition to employing postdocs that a survey is filled by every postdoc at fixed times of their employment, and PUBLISH THE RESULTS

Proven or promising external resources or approaches

No response

Response 1206

Perspectives on the postdoc roles and responsibilities

The postdoctoral position is reserved for an individual who has proved themselves to be capable of performing independent research, but still needs additional training (scientific and professional), publications, and funding to be competitive for a tenure track position. The nature of the science to be completed is at the discretion of the primary investigator prior to arrival. In short, I view this position as a bottleneck/weeding out period to get a scarce tenure track position.

Fundamental issues and challenges

1) The unlikelihood of obtaining a tenure track position combined with a dwindling timeline creates a sense of dread
2) The expected value return (# and quality of publications) of a postdoc applies higher pressure and imposter syndrome
3) Less mentorship from PIs

Existing NIH policies, programs, or resources

Great pay (despite what many say), great health care, great paternity leave, many mental health resources

Proven or promising external resources or approaches

Improved protection from abusive PIs.

Response 1207

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

I am a 5th yr PhD student looking for postdoc positions and most of the universities I want to apply to do not pay enough for me to afford a place to live. Salary alone is making me afraid I will not be able to survive while doing a postdoc, even though I will have a doctoral degree.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

Increase the salary

Response 1208

Perspectives on the postdoc roles and responsibilities

The postdoctoral fellow is a fully-trained scientist who is engaged in a fellowship to advance their learning in a particular skill or set of skills. They also provide enormous value to the laboratory by acting in the roles of mentor to PhD trainees and other staff, leaders on multiple projects, and overall workhorses with regard to manuscript writing/preparation. These activities together with grant writing will provide the postdoctoral fellow with experiences valuable when they work as independent PIs.

Fundamental issues and challenges

A fundamental issue has been the compensation for these highly trained fellows. The current rates do not adequately compensate the fellow for their existing expertise, and without "cost of living" adjustments for different parts of the country, it's quite a challenge to find and maintain postdoctoral fellows, particularly when they can take faculty positions that pay double.

Existing NIH policies, programs, or resources

Many funding organizations, including foundations, look to NIH to provide the going rate for postdoctoral fellows. Without support for fellows starting here, it will be a challenge to recruit fellows moving forward.

Proven or promising external resources or approaches

Perhaps this increase in pay may come with mandatory postdoctoral training seminars sponsored by NIH to increase overall quality of trainees, but that's only a suggestion.

Response 1209

Perspectives on the postdoc roles and responsibilities

The role of a postdoc is to prepare one for a career as an independent researcher. As a clinical psychologist, a postdoc is also an important time to gain clinical hours for licensure. It is an important time to gain mentorship about how to be successful as an independent researcher and grant writing experience. I also view this as a time to begin to develop an independent line of research

Fundamental issues and challenges

The pay for a postdoc is a significant barrier to recruitment and overall quality of life. After 6 years in graduate school obtaining a PhD on a very low salary, it is challenging to accept a postdoc in many parts of the country because the NIH postdoc salary guidelines are so low it makes it difficult to live, especially if you are also training to pay off student loans. Additionally, often postdoc benefits at universities or academic medical centers are very poor. This led me to turn down postdocs at desirable institutions because the cost of living was way too high for the salary, especially given the years of grad school I just completed to get my PhD.

Further, when I was looking for a postdoc research position in the field of clinical psychology/neuroscience, often the postdoc positions leave little time for independent research, manuscript writing, and grant writing, which were all key skills I was hoping to gain while on postdoc. Instead, the postdoc often runs participants for a PIs grant, serving more of the role of a graduate research assistant. I believe this type of postdoc makes it harder to move from the postdoc level to the a faculty position and results in many trainees completing multiple postdocs with very low salaries to make up for the lack of experience before they can successfully land a tenure track faculty position.

Existing NIH policies, programs, or resources

There are many institutions that do not have the funding or resources such as a T32 fellowship or Clinical and Translational Science Fellowships. Outside of programs like this, there is often no structure to a postdoc position and it can be challenging to know where or how to receive support. While there are often networking or training opportunities at various institutions/conferences, these often come with a fee and if the lab is unable to provide funding, the postdoc is left to pay for this out of pocket. Postdoc benefits often do not come with funding to attend trainings such as this. Additional resources at the university level to provide support regarding mentorship, the transition from postdoc to faculty, grant writing support, etc. would be beneficial.

Proven or promising external resources or approaches

Improved salary and benefits

Response 1210

Perspectives on the postdoc roles and responsibilities

A postdoc position is a training position for those highly skilled individuals that wish to pursue a career in academia.

Fundamental issues and challenges

Money. All postdoc positions that I have seen are underfunded. Why would a PhD want to make half as much as they could in industry? The old paradigm of "because I had to suffer through postdoc, so do you if you want to be a professor" is apparent in the salaries offered to postdocs. Top talent is funneled into industry and not academia because industry can pay more.

Existing NIH policies, programs, or resources

Either change the culture that dictates a professor must first do a postdoc, or pay postdocs as much as they could make in industry.

Proven or promising external resources or approaches

Job satisfaction would greatly improve commensurate with compensation and work-life balance. Pay them more, and allow flexible work schedules.

Response 1211

Perspectives on the postdoc roles and responsibilities

It is a structured and mentored training position with a training plan well-designed by both, the mentor and a postdoc. This plan should be reviewed periodically (6 months to a year) and revised per progress in research and professional development, including opportunities from the mentor and institute to foster training environment to meet competitive nature of academic faculty position instead of investing heavily on 'projects and not people' mentality. Postdoc should see themselves as in training phase while taking an (semi) independent position to lead the project with respect to experimental design, execution, and timely delivery of outcomes, including publication(s).

Fundamental issues and challenges

1) Base salary scale is significantly below standards, i.e., for the training and skills a trainee can bring to the lab, salary scale are subpar, even ignoring industry norms.
2) Mentors should have a liberty and budget to focus on their trainees' development and hopefully should have less stress dealing with their own career and project life or toxic culture of publish or perish, e.g., given archaic modular budget of R01 that has not changed since 1990s.
3) Focus on research impact over mere number of publications when scoring training grants.
4) COVID-19 was real and please account for impact on candidate productivity due to factors outside of their control to get reagents and get things done with changing work environment.

Existing NIH policies, programs, or resources

1) Fix the fractured K99/R00 mechanism. Makes no sense to let postdoc in their 4+ years wait for more than 1.5—2 years towards K99 effort given majority needs to apply for revision. Career development plan and K99 phase has a little value for an awardee in their sixth year of postdoc (after multiple attempts) who will (and should) apply for tenure-track by leveraging R00 level of funding. Instead, allow an option to remove K99 phase of award and use that budget to either make payline more flexible and/or add more budget to K22 or similar mechanism.
2) Support more independent positions at NIH intramural program. Stadtman program is great but overly competitive and should allow more applicants to at least get interviewed than merely selecting the same pool of outstanding candidates who sure are outstanding but they do—by nature of selection criteria per publications over fitness to the program—appear at all places, leaving the rest being deemed not worthy by majority of academic places.
3) Allow postdocs without citizenship/LPRs to apply for more grants than K99/R00.

Proven or promising external resources or approaches

1) Criticism aside, I certainly commend tireless efforts by NIH to provide such research funding and their inability to grant more trainees and PIs funding because of budgetary constraints. Similar to Cancer Grant Challenges (NCI—Wellcome trust partnership), partner with non-profit research foundations (Wellcome Trust, HHMI, etc.) or I would argue even with for-profit pharma and tech sectors to increase money pool for funding.

2) Please focus on research impact and fitness of candidate's proposed research and candidate's skills to grant's objectives over focusing on mundane criteria of number of publications and awards to support trainees who may not be worthy of scoring overall impact score of 1 or 2 but rather 3 or 4. Know that trainees—in today's biotech and inter-disciplinary age—have several options to quit academia and go to industry not for just better pay but for better (mental) health. They are not staying in academia for far too long at the expense of huge opportunity cost just because they do not have other options but rather they would love to do academic research and do high-risk, high-reward science only if you allow them a chance.

Response 1212

Perspectives on the postdoc roles and responsibilities

I don’t view post-docs as a positive experience. The amount of workload is extreme with minor pay increase. Additionally many companies are negating a need for it to get a job in industry.

Fundamental issues and challenges

Pay! The compensation is little with expecting sometimes double productivity compared to a graduate student. Extreme demands and minimal compensation make the position undesirable.

Existing NIH policies, programs, or resources

Pay more! I think there’s a start to enhance payment but also minimizing extreme expectations as well.

Proven or promising external resources or approaches

I think you could also host workshops for post-docs, (Mock interviews, certification courses and/or some subsidized childcare)

Response 1213

Perspectives on the postdoc roles and responsibilities

I view my postdoctoral position as a transition to independence and a more permanent position in academia. That being said, the academic environment presents multiple challenges, so I am also considering other opportunities/possibilities for my future career.

Fundamental issues and challenges

I moved to the US in 2021 from Switzerland, where I did my PhD.

- First, finding a postdoctoral position in the US during the pandemic was particularly hard, and I had to take take my current position without visiting the lab. There was no organized way to apply for positions (no recruitment programs or similar) and I found my position circumstantially, via my mentor’s connections.
- Finding housing was particularly challenging. The waiting time for university housing was over a year, and housing outside the campus was more than half my net salary. The university housing was slightly cheaper and the place I got is very comfortable, but I would still have a very hard time affording it without my spouse.
- Doing research is hard but I actually enjoy problem-solving **and challenges** in science. What causes a lot of unnecessary frustration is the mental power I devote to arrange my finances. As a second year postdoc in the US with 3 degrees and more than 10 years experience in academic research, I feel I should not have to worry about paying my rent and my groceries. As a PhD student I felt that I can sacrifice some comfort for acquiring an academic degree, but now I just feel unappreciated.
- The publication system also feels very difficult to navigate. I have done a lot of work that has produced negative results, that I will probably not get any credit for.
- I also find the career dependency on individuals’ publications very problematic. It is very clear that I will not get grants or my next position without publishing well, but I do not want to compromise the quality of my work by publishing too early, or trying to cherry peak and “oversell” my results.

Existing NIH policies, programs, or resources

As an international scholar on a non-immigrant visa, my options for funding by NIH are extremelly limited. I do believe that funding schemes could be expanded to include international scholars, especially as labs in the US are actively recruiting postdocs from all over the world in their effort to built diverse & dynamic teams.

Proven or promising external resources or approaches

No response

Response 1214

Perspectives on the postdoc roles and responsibilities

My view on the role of a postdoc is to independently generate research questions and data. This also includes being able to independently form and successfully publish peer reviewed manuscripts.

In my mind the difference between a successful and unsuccessful postdoc is the degree to which the chosen experiments and data push the field forward. I think staff scientists are similar data generation specialists, but postdocs must also do the intellectual work of knowing the current state of the field and work to improve that either through new technologies or refined experimental design.

Fundamental issues and challenges

It is a huge pay cut to be a postdoc. I am fortunate in that my mentor supports a reasonable work-life balance, so I feel that the value lost in paychecks is gained in that flexibility. However in turning down industry offers I received at the end of graduate school I reduced my starting pay by nearly 200% (ie 58k vs 160k+).

Existing NIH policies, programs, or resources

More money specifically devoted to training staff bench workers. As it stands the K01 mechanism aims to fund researchers with an eventual goal of running an R01 driven research program. There are a potentially people who would like to stay at the academic bench but do not want to run their own research program. If the NIH values these people, either separate funding mechanisms or more flexibility in R01's to fund this type of position.

Proven or promising external resources or approaches

Most of this listed items will be lab/PI dependent, so I'm not sure a general fix exists. Better salary is the only clear option that would have across the board support and impact for postdocs at-large.

Response 1215

Perspectives on the postdoc roles and responsibilities

Exploitation role

Fundamental issues and challenges

Pay, expectations, hierarchy, poor benefits

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

RAISE WAGES

Response 1216

Perspectives on the postdoc roles and responsibilities

A postdoc position means an opportunity to advance and expand your skill set, so you are better prepared to assume the role of a PI in academia. Training related to teaching, mentorship, and leadership, are also very important for me during my postdoc training. The expectation is that you finish a period of several years working in a Lab with more know-how about how to operate in team work with different people, with a new research technique that are relevant to the field you want to advance later in your career, and to publish good quality papers participating intensely on the process of producing the data, writing the draft and taking care of the peer review process. The postdoc position is not a necessity to become a PI, but it is an important position to take when you feel you have more to learn in the field or you want to expand your skill set to other areas that are important to you.

Fundamental issues and challenges

For recruitment and retention, one of the main problems are salary and benefits. You need to receive a salary at least comparable to the industry for similar positions, otherwise a postdoc may feel more inclined to work in the industry if they want to start a family, for example. Good salaries and benefitis and other arrangements for the position that aim to provide a more stable life and financial condition to the postdoc will surely increase recruitment and retention.

For quality of life, it is crucial that supervisors and PIs receive training related to mentorship and leadership. The vast majority of PIs are ill prepared to handle conflict, organize teams and tutor people that want to enter or stay in Science, which leads to bad retention and bad work life balance. I believe that, just spending a few resources and time to make mentorship training mandatory to every PI would help a lot with the quality of life of not only postdocs but everybody involved in a lab team.

Existing NIH policies, programs, or resources

Personally I don't receive notice of many NIH resources and programs, so I'm not well aware of what is already provided. I did participate in some webinars about work life balance and grant writing, which I think are good in general. The problem with those resources is that they may not be locally available, where you can have more direct access to it.

NIH policies seem very good to me.

Proven or promising external resources or approaches

Providing a system or program that warrants the postdoc with research and financial support after his postdoc, without the requirement of achieving a professor position, may help with retention and recruitment.

Discussions about the expectations of the PI or supervisor are proven to be a solid strategy to improve quality of life and overall satisfaction with work. Even though many institutions have policies implemented regarding this, I believe it is necessary to make more efforts in that direction to ensure Lab heads are aware of their "style" affecting the quality of life and work of their lab members.

Creating a program that accepts "high risk" project specifically from postdocs, even with low budget, could also increase job satisfaction.

Response 1217

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

Postdoc compensation in federally funded grants is grossly insufficient and is going to eventually kill our academic establishment by making postdoctoral work so undesirable that academic research will become impossible.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1218

Perspectives on the postdoc roles and responsibilities

In my mind, an academic postdoc position is meant to prepare an individual for a future in academia, so responsibilities include performing independent research, writing manuscripts, helping to manage the lab by training new staff and graduate students, and mentoring other lab members. I think academic postdocs would be more worthwhile to individuals not interested in staying in academia, if the pay was comparable to industry.

Fundamental issues and challenges

Salary and benefits, full stop. Postdocs are some of the most highly specialized workers in the country, usually with 10+ years of experience, and they deserve salaries and benefits commensurate with their experience and the value they contribute to the university and to the country. Science would not function without academic postdocs, they are our backbone, but we force talent out of academia because they can't afford to stay, especially after being underpaid and undervalued for 5-6 years during their graduate trainings. Postdocs need salaries adjusted for the cost of living in the expensive cities where top universities are. They need childcare and health insurance for dependents and partners. If we can provide these basic things that industry easily offers postdocs, we can retain so many more talented people and solve important biomedical problems. Additionally, I think all PIs accepting postdocs should be mandated to take a DEI training each time a new NIH-funded postdoc joins the lab. While I think cost of living is a wider spread issue overall, abuse by PIs, especially of postdocs from historically excluded backgrounds, also force talent out of academia, to industry with HRs and the ability to fire abusers. Biomedical problems affect diverse populations, and we NEED a diverse group of scientists to address these problems. The NIH must do better.

Existing NIH policies, programs, or resources

SALARY. Raise the graduate student and postdoc expenses CONSIDERABLY. We all deserve living wages to support ourselves and our families.

Proven or promising external resources or approaches

No response

Response 1219

Perspectives on the postdoc roles and responsibilities

Time to publish papers and work independently. Training to become a PI by an experienced PI

Fundamental issues and challenges

Long hours, low pay, and poor benefits.

Existing NIH policies, programs, or resources

Higher pay for post docs.

Proven or promising external resources or approaches

Increase the minimum postdoc salary set by NIH

Response 1220

Perspectives on the postdoc roles and responsibilities

Until recently I was a T32-supported postdoctoral fellow. I saw my postdoc fellowship as a time to establish my research expertise, learn new skills, and understand the available opportunities for me to pursue research in the next stage of my career. In particular, I used this time to develop and submit papers in my area of interest. Attend conferences I had never been to, but was always interested in, and I also began pilot research projects that had potential to expand into larger research studies. My postdoc was a time in which I was afforded protected space to build new skills that would make me competitive in the job market. I also viewed my postdoc as a time in which I could evaluate how I would like an academic career. To this end I wrote several grants and familiarized myself with different funding mechanisms, and I also was able to get clinically licensed. I explored a variety of settings in which I could apply my unique training (academic and industry). I saw part of my job as building my professional career in ways that mutually benefited the group where I was working. Part of my role as a postdoc was to analyze data and write papers related to projects our group was supporting. It was within scope of my role to support ongoing research in my place of employment by lending my unique expertise on projects as well as ensuring research operations were smooth (i.e., ensuring recruitment operated as expected, managing IRB submissions, setting up databases and analyses). Overall, postdoc was a unique opportunity to focus on getting skills I wanted for my career and assess where and how I wanted to build my career all in ways that benefited the setting I was working in.

Fundamental issues and challenges

The most significant challenge of postdoctoral training is the limited stipend. The NRSA stipend is and was below the cost of living in the area in which I completed my postdoc. Had I not been privileged enough to be able to take out loans in both undergrad and grad school, lived with my partner who had a job outside of academia, and lived in a home my partner owned, I would not have been able to pursue NIH postdoctoral training. In truth, the draw of industry salaries or faculty positions (all of which I was highly qualified for) made it a challenging decision to choose to pursue postdoctoral training. While I knew there were skills I wanted to gain as part of my postdoc, I was only afforded the space and time to pursue that training because of the privileges noted previously. Even so, without knowing if I could secure a job in the geographic location in which I completed my postdoc, it was extremely difficult to choose to pursue a postdoc. I was not sure if I would be uprooting my partner for 2 years during a critical period in our lives. Especially on the heels of having moved for a 1-year residency the previous year. To this end, delaying important life events was a significant challenge during my postdoc. Because of the lack of financial and occupational stability, my partner and I delayed getting married and having children. These are major factors trainees consider that contribute to quality of life and longevity in academia. Moreover, and this is a smaller aside, benefits for postdocs (i.e., insurance) are usually worse and more expensive than for faculty or staff. Therefore, in addition to forgoing a salary more than double (often) the postdoc stipend, postdocs must pay more for fewer benefits.

Existing NIH policies, programs, or resources

One of the most critical and life changing programs that I was able to participate in was the NIH loan repayment program. Being a recipient of this grant substantially reduced my debt and eased a significant financial burden. An expansion of this program would be a welcome change for trainees. Additionally, expanding allowable T32 costs to be used for moving expenses and other relocation requirements would be a substantial help. As an alternative, enabling postdocs (incoming and current) to apply for administrative supplements for life-related costs such as relocation and childcare would also be substantially useful. While childcare costs are addressed to some extent as part of NOT-OD-21-177, the $2,500/budget period is woefully insufficient to cover childcare costs that are over $2,000/month in many urban areas. In the event that building a family is a goal for some postdocs, having grants that can help postdoc researchers build a family during a critical period in their lives (often one that has age-related limitations) could do a great deal to improve postdocs quality of life.

Proven or promising external resources or approaches

Building more paths to full employment as faculty or in industry following postdoctoral work would be an important next step for NIH. There is a shortage of faculty positions open to support all postdoctoral trainees. Building pathways to full employment such as public-private industry partnerships, sponsored faculty lines, etc. would be a tremendous step towards making biomedical research a more sustainable endeavor for trainees. I see industry internships as a great example of these kinds of pathways. Having an internship that converts to a full employment position would be a revolutionary change to postdoctoral training in that it would increase stability and could afford researchers protected time to obtain funding for their salary and work. Programs like the K99/R00 could be expended to accomplish this, but this would need to be done in conjunction with academic institutions to ensure faculty lines were available. Another example of this is UC Santa Cruz's Presidential Postdoc which is a funded faculty line following a two-year postdoc.

Response 1221

Perspectives on the postdoc roles and responsibilities

Responsibility:

1) Independent research design
2) Secure funding
3) Execute research and mentorship of lab members
4) Present research to secure future positions
5) Move on to a future position
6) Acquiring new skills
7) Networking

The result is supposed to be a self-guided research project in a lab with similar goals. Most post-docs appear to be focused on a professors work similar to grad school, restricting the actual research that can be completed.

Fundamental issues and challenges

Cost and lack of systematic support. Most positions are highly related to "who you know" and there is an emphasis on doing research for a lab. The lack of flexibility to work is a big issue.

Maltreatment in academia itself, the incentives for research are poisonous in a general sense. Publish or perish is the only way to advance and that means sacrificing the fundamental things that matter to me as a research. So at that point, why should I care? Why should I be paid pennies to do work that I don't want to when i can do the same thing in industry and make a bunch more.

Mental health support is abysmal, even when programs are implemented they are token at best. My university was ahead of the curve by hiring a councilor but it's barely functional.

Frankly I've met barely a handful of other grad students who wanted to go into post docs because of the level of abuse. We are stuck dependent on a professor for 4-5 years and post doc is just an extension of this. The system feeds those who are good at grifting and leeching credit while harming those doing the fundamental research required to push science forwards.

Universities do not support one of their biggest form of funding to the university via intellectual property.

Existing NIH policies, programs, or resources

Frankly a restructure is required. Academia as a whole is toxic. This will probably be dismissed as dramatic or unhelpful by a group of reviewers already firmly entrenched. But it is the truth.

We feel tricked and abused by this system and are not comfortable continuing. We are tired and have not been supported through our whole career. Undergrads are sucked for money, grad students are exploited at a level that make McDonald's drive through compensation look good, and now post docs get to just perpetuate the suffering and exhaustion. We are tired and have the opportunity to take care of ourselves instead of being drained by this system for the aggrandizement of a group of enshrined professors.

Proven or promising external resources or approaches

Look at industry, there's a reason they are stealing all your candidates.

Response 1222

Perspectives on the postdoc roles and responsibilities

Postdoctoral position implies further training; however, the main role shifts to expanding individual leadership/thinking rather than simply absorbing new techniques. Mentoring should also be emphasized either for a shift to industry or further academic roles.

Fundamental issues and challenges

Postdoc pay is uncompetitive compared to industry and provides no advantages in terms of training. Why would a graduate student pursue a postdoc for a meager pay increase when similar training can be received in industry with a major pay increase? With postdoc pay, in many locations, it is impossible to start a family, own property, or otherwise pursue an independent life.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

Academic post docs have demonstrated potential in balancing the training of individuals while still granting a sustainable level of pay.

Response 1223

Perspectives on the postdoc roles and responsibilities

I see a postdoc as a required step to becoming a PI, but I am not sure how much value it adds. You typically have to spend another 5-6 years in a poorly paid position working long hours. Personally, the combination of little pay and long hours is slightly insulting to someone that has already spent years in graduate education. It only seems worth it if you want to go into academia, otherwise industry will give you a job right out of your PhD with reasonable hours and 1.5 to 2 times the pay. To my view, the postdoc just makes you do another research project to show that you can succeed in more than one lab and therefore deserve to be a PI in industry or academia. However, a postdoc provides none of the critical training that PIs require: management, financials, social competency, etc.

Fundamental issues and challenges

Why would an individual that has already spent over a decade (undergrad + PhD) being poor and overworked want to continue being poor and overworked. This prevents people from getting settled in their lives and starting families. There are other career options to pursue that give both better work-life balance and better pay, so why not go there?

Existing NIH policies, programs, or resources

I don’t know about existing policies, but consider adding management training to the postdoc: financials, interpersonal conflict, leadership, communication, and other core components that make someone a successful manager because that’s what being a PI is about.

Proven or promising external resources or approaches

No response

Response 1224

Perspectives on the postdoc roles and responsibilities

The way I view a postdoc, it is a transitory position where you fine tune your bench skills and establish an independent project for a potential future research position. This can be either preparing your skillset for industry, academia, or other scientific fields.

Fundamental issues and challenges

The main issue with retention of postdocs is the balance between the stressful work environment and the salary provided. The constant pressure of publications coupled with the low salary in comparison with other Ph.D. positions (ex industry), makes it much more difficult for job retention, Additionally, it is much more difficult for those postdocs who are caring for children or family to maintain a balance between work and life responsibilities. Using myself as an example, I can survive with the currently salary (not married, no student loans, US citizen), but I fully understand how difficult it must be to rely on this job as a breadwinner for the family. Overall, the current salary and benefits just cannot compete with the current market.

Existing NIH policies, programs, or resources

Just to list a few, open NIH training grants to visa workers under the stipulation of them working in a US lab. The vast majority of postdoc are under a visa and encounter difficulties obtain additional grant opportunities to fund independent projects. Additionally, some form of assistance (either legal assistance or orientation on the process)so that these worker visas can transition into a permanent resident status. Establish a postdoc UNION to defend post doc interest and avoid work abuse.

Proven or promising external resources or approaches

No response

Response 1225

Perspectives on the postdoc roles and responsibilities

A Postdoc is a position that helps diversify a recent graduates fields. It is for branching out and collecting specializations for future use.

Fundamental issues and challenges

Postdocs are inherently on soft funding and have to produce a huge amount of productivity to be worth it.

Existing NIH policies, programs, or resources

Fellowship grants to be more broad and supportive for postdoctoral students.

Proven or promising external resources or approaches

Make postdoctoral positions competitive with industry jobs. Most students I work with are forsaking academia for industry.

Response 1226

Perspectives on the postdoc roles and responsibilities

First and foremost, postdocs should be valued as having an advanced degree, and be treated as such. They are highly skilled researchers, but are not often viewed that way in terms of university policy. Anything the NIH can do to support that view would be beneficial.

Fundamental issues and challenges

Quite simply, the pay of postdoctoral scholars must be increased to match cost of living increases and more directly compete with industry. There are numerous issues with this increase, however, including increased burdens on already tight R01 budgets. As a result, R01 modular budgets should increase to reflect current costs of living and provide a sufficient level of support for PI salary, postdoc salary and reagents. Alternatively/additionally, provide additional funding mechanisms to provide fiscal support for postdoctoral scholars, recognizing that they hold PhDs. Ideally, additional support for postdocs could come from universities, directly, although I see that as unlikely as many universities don't recognize the value of a postdoc in terms of research money brought to the university (either directly or through contribution to an R01).

Existing NIH policies, programs, or resources

1) Provide federal guidance to universities that postdoctoral fellows are to be considered staff and not students, and that this does not change as postdocs go onto/off of fellowships/grants. Often in academic institutes, postdocs are flexibly treated as staff or student depending on which is more convenient (i.e. less fiscal or other resources required). Postdoctoral fellows have an advanced degree, and therefore should no longer be considered as students.
2) Redefine postdoctoral NRSA positions relative to the above point, such that postdoctoral fellows aren't fiscally or otherwise punished by universities for securing federal funding. When I went on my F32, my pay ended up decreasing significantly because I could not be considered a staff member anymore, therefore my insurance benefits changed, resulting in an increase in out of pocket expenditures. Fortunately my PI at the time covered the pay loss, but this caused unnecessary stress.

Proven or promising external resources or approaches

No response

Response 1227

Perspectives on the postdoc roles and responsibilities

I got a PhD in biochemistry from 2008-13. I loved the work I did and consider myself a successful researcher. My lab was supported by multiple NIH and HHMI grants/programs. However, I decided to leave academia due to the near-poverty wages offered to postdocs. I moved to non-science industry where I

was paid a good wage with great benefits. I am sad that I wasn't able to stay in science, but as someone who wanted to start a family and buy a home, it was just not a reasonable option.

Fundamental issues and challenges

To me, the low pay for postdocs is by far the biggest issue. If you fix that, almost everything else will get better. The low pay also hurts diversity in science, because most people who are able to stay on as postdocs have families with money to support them, or at least they don't have large debts or families that need their financial support.

Existing NIH policies, programs, or resources

Dramatically improve pay and benefits.

Proven or promising external resources or approaches

No response

Response 1228

Perspectives on the postdoc roles and responsibilities

Postdoctoral training is a mechanism that basically asks a person to redo a PhD after completing a PhD so that they can obtain a tenure track research position. The pay is not adequate to support a person who has a child unless there is a partner with a very high income.

Fundamental issues and challenges

It has now become necessary to complete a postdoctoral fellowship to obtain a tenure track position in any research institution. Postdoctoral work requires physical work in a lab for pay under the poverty level in most cities. It prolongs training by 4-8 years after the PhD has been completed. These days, it is hard to get into graduate school straight out of college (without research experience as a technician). A PhD takes about 5-7 years. If a person completes a postdoctoral fellowship, they start the academic job market in their mid thirties, which is too late for many women to start thinking about bearing children. The students I have mentored (and I) feel that the extent of time that it takes to now "train" for an academic position excludes women who want to have children from academic careers. Even the most talented students who wanted careers in academia are less enthusiastic because of the postdoctoral fellowship requirement makes it difficult if not impossible to have children without a partner with a lucrative career.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

Increase funding for postdoctoral salaries and for PIs to fund postdocs so that they can afford childcare. Childcare for one child is about $25,000/ year in my area, and I do not live in the most expensive city.

Response 1229

Perspectives on the postdoc roles and responsibilities

The academic postdoc is a transition to faculty. During this time one should learn about management, lab set-up, budgeting, obtaining funding while also increasing publishing record and acting as an independent scientist.

Fundamental issues and challenges

The pay is barely live-able and overlaps with a time in life that often includes marriage, family decisions, real estate purchases etc so the pay is very restrictive. This is an in-between where one is not considered faculty but not a trainee either, so they often miss out on resources and support but also social and university events, networking etc.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1230

Perspectives on the postdoc roles and responsibilities

An opportunity to do much more independent and self-guided research after having acquired the skills to do so during the PhD.

Fundamental issues and challenges

Postdoc positions don't pay enough, especially since I'm an older and married graduate student.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

Pay more and provide better benefits (like lunch).

Response 1231

Perspectives on the postdoc roles and responsibilities

From my perspective, it seems like postdocs are just graduate students with more experience. They get larger workloads and more responsibility, but otherwise perform tasks and research similar to what is expected of a graduate student.

The expectation is that this type of role will allow a person to transition into a professorship or other higher-level academic position. Though, from what I've observed, most people can't find an opening for such a leap, and end up stuck in various postdoc appointments for an extended time.

Fundamental issues and challenges

Being a graduate student is an unpleasant experience. Being a postdoc is worse, because they have greater obligations, minimally improved pay, and fewer opportunities following the completion of their appointment.

Many postdocs I've spoken to have compared their experience to 'failing to launch' into a good career, and ending up stuck. There are far too few professorship opportunities proportional to the demand for postdocs.

Existing NIH policies, programs, or resources

Either more positions to grow into in academia (professorship, or something similar that actually makes for a decent career), or better pay for postdocs themselves, so the job doesn't feel like such an overworked and unappreciated dead end.

It's worth noting that by the time someone finishes their PhD and can become a postdoc, they're likely around 30 years old. This is a time when people need to focus on their career and start saving money if they ever hope to retire. Some people will want to have kids at this time. and a postdoc simply is not a career, and does not pay enough to support a family or make meaningful savings. Especially not for the level of specialized skills and effort it entails.

I do not know automatically which NIH policies/programs/research relate to these issues, but I presume (hope) that some do.

Proven or promising external resources or approaches

None that I know of. Frankly, we all know why this postdoc shortage is occuring.

Response 1222

Perspectives on the postdoc roles and responsibilities

It means management, communication and leadership to me. A postdoc is not just a learning role, but also a connection role.

Fundamental issues and challenges

I heard the stress and the salary of postdocs can be intimidating for people who want to pursue this job.

Existing NIH policies, programs, or resources

More support (such as mental health, training opportunities, and organizations) for postdocs as they are usually neglected by the institutions when they don't fall under a formal employee or a student category

Proven or promising external resources or approaches

No response

Response 1233

Perspectives on the postdoc roles and responsibilities

A post-doc's primary purpose is to work to get more publications so that they can then pursue academia. The necessity of completing a post-doc for industry jobs seems to be quickly decreasing. Post-docs are expected to continuously produce data as their primary goal but are often given additional tasks such as mentoring permanent graduate students and rotating graduate students as well as lab techs and undergrads (depending on the lab and institution), and this time dedicated to training is not expected to impede on productivity. If there is not a research scientist or tech in the lab as well, many lab tasks end up falling on their shoulders since they would be considered more senior in the lab.

Fundamental issues and challenges

Money. Post-docs are disgustingly underpaid typically, and their salaries are not monitored since they are not part of an official training program (i.e. a graduate program). The average post-doc salary is below $50,000 which is not much of a step up with their doctoral degree. It seems difficult to impossible to support a single person, never mind a family, on a post-doc salary, especially if their institution is in a city. While graduate students usually have the institution they are in to support their salary increases with inflation, post-docs are completely dependent on their PI's grants if they are not individually funded already, and since grant awards have not increased significantly recently, post-doc salary therefore has not increased. There also is a lack of training programs and communities for post-docs compared to graduate students and other lab members. Overworking post-docs as well as underpaying post-docs are the two main deterrents, in my opinion, that graduate students are less likely to pursue post-doctoral training.

Existing NIH policies, programs, or resources

1) Funded post-docs should have a committee so their work does not get held
2) Salary increase
3) More workshops supporting post-doc transition into academia/other careers (for those you fund at the minimum)

Proven or promising external resources or approaches

No response

Response 1234

Perspectives on the postdoc roles and responsibilities

A postdoctoral scientist should not be considered a trainee or student after the highest level of education (i.e., PhD) has been obtained. As such, an academic postdoc should be entitled to a competitive pay rivaling industry, as well as benefits that reflect a job where a doctoral degree is required. The academic

postdoc, in turn, shall provide be held to PhD-level standards of research and thinking, as well as mentoring/training if agreed upon.

Fundamental issues and challenges

Insufficient pay and benefits (location adjusted), for the level of education required, lack of work-life balance in the field, lack of support for parents

Existing NIH policies, programs, or resources

It isn't postdoctoral training, it's a job. Competent baseline salary along with competent benefits

Proven or promising external resources or approaches

No response

Response 1235

Perspectives on the postdoc roles and responsibilities

The academic postdoc position is a stepping stone in training for those interested in careers in academic research. The goal of most postdocs is to complete a project independent from their PhD research, in a new lab, so that they can gain increased experience in project development and completion, publish additional papers under their name, and refine other aspects of their professional development (i.e. teaching experience, learning new techniques, networking) as needed.

Fundamental issues and challenges

The alternative to a postdoc position for many recent PhD graduates is to enter industry roles, which often promise higher pay, better benefits (healthcare, parental leave, childcare options), and more regular working hours.

Existing NIH policies, programs, or resources

The current NIH-recommended postdoctoral stipend could be increased to adjust for inflation from the past several years, and to make the postdoc role more competitive when compared to industry roles that are the alternative for most graduates. Additionally, the recommended stipend could vary depending on cost of living at the specific institution, rather than being the same number across the nation, which leads to increased differences in pay between postdoctoral and industry positions in high cost of living areas.

Proven or promising external resources or approaches

No response

Response 1236

Perspectives on the postdoc roles and responsibilities

I honestly don't know the purpose of a post-doc.

Post-docs are for PhD students that didn't do a good job during their PhD and couldn't get another job (e.g., as a professor or for a company).

Fundamental issues and challenges

The compensation given to a post-doc (salary, resources, respect) does not match the responsibilities (can be responsible for managing multiple people, securing their own funding, managing multiple projects). Ultimately I don't think most post-docs meet expectations and maybe don't deserve better compensation.

Existing NIH policies, programs, or resources

Not sure why a post-doc is needed before becoming a professor. People should be challenged more during undergrad and PhD training, and their ability to be a professor should be determined earlier on. No need to have a post-doc system. If a professor wants more qualified scientists that already have experience, then pay them appropriately.

Proven or promising external resources or approaches

I think the way companies operate could be a better approach. People's responsibilities are constantly increased as they gain experience and prove they are capable. And compensation increases along with responsibilities. No need to wait 5 years to 'promote' someone from a PhD to a post-doc. This should happen faster, and in a more continuous fashion.

Response 1237

Perspectives on the postdoc roles and responsibilities

The postdoctoral position means to me:

- The opportunity to do research (as I have no own lab/group, I couldn't do research anymore if I were not a postdoc)
- the responsibility to teach/guide/be an example for younger scientists, to support them with my experience
- the responsibility to do high-quality research and to move my research field forwards
- the responsibility for my projects
- the responsibility to develop my career/myself to be a better researcher/teacher
- the responsibility to communicate/talk about science and its positive impact outside of the scientific community/ to promote scientific thinking in the society
- bad/little chances for career development; my university offers a lot of career development programs for junior faculty members; there are no such programs for postdocs
- being excluded/discriminated/used by the system: as a foreigner, I work as hard (or, in my particular case, even much harder) than my US colleagues, yet I can not apply for F/T/K awards (apart from K99), which means much worse chances for an academic career. Since I noticed this discrimination, my motivation to work in US academia has decreased a lot.

Fundamental issues and challenges

Postdoctoral "training" is supposed to be a combination of job and training. However, it is not; it is a badly paid job with little chance to develop:

- there is no structured training, no curriculum, and no obligations for the faculty to train postdocs, the "training aspect" is not seldom reduced to an hour exchange about the project every few weeks
- this "training character" is used to justify the salary, which is lower than in industry; de facto, as there is no postdoctoral training, this salary is not just.
- the postdocs at a lot of universities have no right to apply for grants even if they are the main intellectual contributor to their project
- postdocs accommodate with low salary/no right to apply for grants because they hope to get themself a faculty position one day. Yet the chances for that, especially for international postdocs, are very low.

Altogether with almost non-existing training, low salary, and few chances for a faculty position, it is hard to understand that there are still people who want to be postdocs.

Existing NIH policies, programs, or resources

1) For the institutions that get NIH funding:
    a) introduce mandatory curricula for postdocs; postdoctoral research should be oversight by a committee similar to a PhD program
    b) introduce mandatory specification of training goals and plan how to achieve these goals
    c) introduce mandatory career development programs/mentoring programs, and other development opportunities for postdocs; support these programs by additional funding for institutions that offer them
    d) encourage the involvement of advanced postdocs (if they are the main intellectual contributor to a project) as (Co)PIs on grants
3. Allow international postdocs to apply for T/F/K grants (international postdocs are half of the postdocs in the US and they are an important pillar of US academia; there is no justification for discrimination of international postdocs, and this discrimination damages the science in the US and its reputation)

Proven or promising external resources or approaches

- A lot of universities have elaborated support/career development programs for (junior) faculty. Including postdocs in these programs, or offering similar programs for them would be a promising approach.
- Mentoring programs: postdocs are hired to do a particular job, and mentoring by the group leader/boss is commonly insufficient; external (within or outside the institution) mentoring programs would be very helpful for postdocs.

Response 1238

Perspectives on the postdoc roles and responsibilities

Basically the same responsibilities as being a PhD student, but with additional expectations like more grant writing and lab/personnel management.

Fundamental issues and challenges

Compared to industry positions, a postdoc position involves worse compensation, more expected hours worked, and worse training. There are pretty much no benefits to doing one if you can get an industry position instead, so from a career standpoint it only makes sense to do a postdoc if you want to be a professor.

Existing NIH policies, programs, or resources

Compensation competitive with industry would make a postdoc position more appealing and would help offset the poorer training and higher working hours expectations associated with a postdoc.

Proven or promising external resources or approaches

No response

Response 1239

Perspectives on the postdoc roles and responsibilities

As someone who will likely have several first-author publications and 10 years of continuous research experience at the end of my Ph.D., I view the postdoc as adding no more value to my career, as I would like to lead a scientific team directly out of my Ph.D. and increasingly think Ph.D. training is sufficient given that so many Ph.D.s in the biomedical sciences have several years of high-quality research experience prior to starting their Ph.D.

Fundamental issues and challenges

Inadequate pay —the NIH modular R01 budget has not changed in decades and yet inflation has raised both the price of research consumeables and cost-of-living regardless of geographic region, placing a burden on both lab budgets as well as postdoctoral salaries.

Existing NIH policies, programs, or resources

Double the modular R01 budget. Full stop. Require a minimum postdoc salary of $70k per year. Require grantee institutions to eliminate artificial tuition for Ph.D. students who have completed coursework requirements to free lab budgets for salary raises across the board.

Proven or promising external resources or approaches

Double the modular R01 budget. Full stop. Require a minimum postdoc salary of $70k per year. Require grantee institutions to eliminate artificial tuition for Ph.D. students who have completed coursework requirements to free lab budgets for salary raises across the board.

Response 1240

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

Livable wage. There is no other way to put it. Institutions do not always pay the NIH suggested stipends and, like we saw with the [redacted for anonymity] strike, they rarely adjust for cost of living. It is a constant struggle. Even without student loans and in the cheapest studio I could find, I started my post doc in LA $100 in the hole every month when I got paid. This is a professional position that deserves to be treated as such. Postdocs are treated like glorified grad students who still have zero outside commitments from lab. We have partners and children. We deserve to make a living that can feed our families. This is the number one reason my colleagues are leaving their postdoc positions right now. Institutions laugh at us when we ask for more money and tell us they can’t afford it. We all know that is not true.

Existing NIH policies, programs, or resources

If PI’s get funding from NIH they should be REQUIRED to pay postdocs at least the NIH recommended stipends. There should also be a policy to account for cost of living.

I’m sure there are a lot of other things that could help me, but I can’t even worry about those things when I don’t even make a livable wage I can survive on.

Proven or promising external resources or approaches

No response

Response 1241

Perspectives on the postdoc roles and responsibilities

Applies skills obtained during PhD training to lead projects in their current lab; more involved in grant writing than graduate students; as a more senior member in the lab, is available to mentor more junior lab members, especially regarding research approaches, presentation and communication skills, and networking.

Fundamental issues and challenges

Salary when compared to industry, quality of life based on the lab and its location, possible mismatch in expectations between PI and postdoc.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1242

Perspectives on the postdoc roles and responsibilities

A postdoc in the academy has shifted from a "training period" to a staff research scientist position. I came to learn a new technique, specifically, and was geographically bound.

Fundamental issues and challenges

Currently postdoctoral positions can leverage trainee status to facilitate visa, but also reduce wages and do not create worker protections. This creates a pool of highly trained employees that are implicitly expected to stay for future promise of the academy at the expense of current wages and familial support. However, our "goal" role of assistant professors have also changed. Administrative burdens, teaching expectations, and competition for funding all contribute to a set of severe pressures with few incentives for stability or protection as a career.

Existing NIH policies, programs, or resources

I was pleased to see parental leave as an addition to F32 training stipends. I believe this could be expanded upon or perhaps extended in high cost of living areas.

Extended R01 budgets would be a huge boon. Maybe a limitation on the # of trainees/PI could prevent an ever increasing number of trainees within the system?

Proven or promising external resources or approaches

Formal learning to lead/mentor programs (maybe akin to the Responsibility in Research) could be implemented to facilitate more efficient training systems to reduce the # years of postdoc is within the system.

Response 1243

Perspectives on the postdoc roles and responsibilities

The postdoc is a job created to allow researchers to learn more before moving on to a permanent position. However, this position has become required if you want to even entertain the idea of having an academic position. In some fields, it is common to do multiple postdocs. For many postdocs you are 30+ years old at a time when you want to start a family or are saving for retirement but are barely paid more than some first-year graduate students even though you have a PhD. I view the postdoc as a sacrifice I have to make in order to be in academia. I had to sacrifice a job where the initial offer was more than twice my current salary with amazing benefits. However, since I have a passion and desire for research and mentorship I took the postdoctoral position.

Fundamental issues and challenges

No one wants to do a postdoc because of the money. It is preventing qualified applicants from considering the positions because the sacrifices are too high. You have minimal to no benefits, bad insurance, no retirement benefits, and a low salary. It is extremely difficult to make ends meet as a single-income household and image if you have kids. Grad students have more support since they are students in the case of family emergencies and maternity leave. Postdocs have nothing because were not students or faculty/staff. Because we are in this middle category we do not qualify for other benefits both students and faculty get such as discounts on public transit. That is something so small that we have been told for YEARS is our of our reach. The cost of doing a postdoc does out way the benefits. There is not a week that goes by that I do not regret turning down industry since in the world we live in everything cost money and you need money to live. I went to grad school in a rural area so the cost of living was lower and although I make a bit more now, but my budget is much tighter because I spend more living in a city on commuting, rent, and food. My current mentor use to run the postdoc office at my institution and she said it has been the same battles for the past 20 years! The excuse is well that's how it was back then so we need to be fair and consistent. That is not a rational argument.

Existing NIH policies, programs, or resources

Make it clear the NIH minimums are minimums and those are meant for the lowest cost of living. Give a table for different cities that show the adjustment. Require appropriate benefits. Make us staff at our institutions. At least give us the same benefits and resources as students and research staff. We have no

advocates at our institutions and our numbers are small compared to the students so our voice is not heard and taken seriously.

Proven or promising external resources or approaches

Academia needs to be competitive. There is a postdoctoral shortage because industry and government are that enticing. I guarantee many of those researchers do not want to leave academia but feel they need to because they can not survive on a postdoc salary/lifestyle. Increase salary and standardize benefits.

Response 1244

Perspectives on the postdoc roles and responsibilities

An opportunity to grow into an independent scientist who can conduct their own research and run their own lab.

Fundamental issues and challenges

The NIH stipend levels are not keeping pace with inflation, or even with the pay for entry-level full-time employee positions such as RAs or lab managers. When a newly hired student who just finished their undergraduate education is making more money than a postdoctoral fellow in the same lab, it becomes very hard for anyone who has any money concerns whatsoever to remain happy with the postdoctoral training opportunity provided by the NIH.

Existing NIH policies, programs, or resources

Adjusting the minimum salary stipend to keep better pace with the salaries for folks outside of academia, or even within it (e.g. lab managers) but not in a training program.

Proven or promising external resources or approaches

No response

Response 1245

Perspectives on the postdoc roles and responsibilities

As a postdoc, I was expecting to find a lab in which I could build up my background in how to be a good PI and help me understand how to start my lab. Regarding the responsibilities of a postdoc, I was expecting to learn how to manage projects and mentor people in the lab beyond the lab work. I am also learning to design, organize and conduct highly specialized and advanced experiments using established scientific protocols and procedures and, in some cases developing new protocols.

Fundamental issues and challenges

I am fresh as a postdoc, and I do not have experience working in another lab. Still, talking with other postdocs, I have heard that the lack of sense on behalf of the PI about the human behind the postdoc and the needs beyond the lab makes harder postdoc retention. this issue makes the postdoc’s personal life unnecessarily more complicated.

Existing NIH policies, programs, or resources

In this issue, NIH has worked well. NIH provides many resources which help postdocs get the background in how to get the independence to start their lab.

Proven or promising external resources or approaches

The NIH could create a platform or environment where the postdocs can interact and start to build the network for future researchers.

Response 1246

Perspectives on the postdoc roles and responsibilities

Broke

Fundamental issues and challenges

Too little pay, not worth the work

Existing NIH policies, programs, or resources

Proven or promising external resources or approaches

No response

Perspectives on the postdoc roles and responsibilities

I see post-docs as something only for people who want to become professors. I am only a first year graduate student, but I think of post-docs as being low paid, and almost like an extension of being in graduate school, just with more responsibilities and freedom, and less academic work. I wish they were advertised more as a phd-level staff scientist role rather than a short term post-doc seemly only used to publish more papers and become a professor.

Fundamental issues and challenges

No response

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

Response 1247

Perspectives on the postdoc roles and responsibilities

It's supposed to be an apprenticeship leading to academic roles but essentially has become a way for the government (as grant funders) and academia to hire qualified scientists cheaply, often with little mentorship or advising.

Fundamental issues and challenges

Salary, poor working conditions, bullying and condescension.

Existing NIH policies, programs, or resources

Proven or promising external resources or approaches

Improving job satisfaction and salary.

Response 1248

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

Low pay, long hours, abuse by PIs, stress have to pay back salary if leave in first year. Can go to industry and earn a much higher salary, work a more regular schedule, and still obtain quality training experiences.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1249

Perspectives on the postdoc roles and responsibilities

I believe postdoctoral fellowships are extremely valuable experiences for the fellows to help prepare them for future careers, especially for careers in academia. Postdocs are also crucial to the success of most labs, including mine.

Fundamental issues and challenges

Pay is a major issue. When individuals are highly trained and can earn a salary that is at least 2-3 times higher in industry compared to what they would earn as a postdoc, they are far less likely to complete a postdoc.

Existing NIH policies, programs, or resources

The policy of not being able to supplement T32 recipients' salary with R01 or other federal funding is a major problem. It creates a situation in which either T32 funded fellows earn a lower salary than their full potential or they have to be supplemented by non-NIH funds. In my institution the latter is nearly always the case (and will become institutionalized as the case, since postdocs recently negotiated a higher salary scale than the NIH scale.). This creates an untenable situation for PIs who want to hire T32-funded postdocs but don't have a steady stream of non-NIH funding. I am currently co-PI of a T32 and there are several great faculty who are affiliated with the program who have outstanding NIH-funded programs but decline to take postdocs on the T32 because of the need to supplement salaries with non-NIH funds.

Also, the NIH needs to realize that pays scales may need to vary by geographic location. Living on an NIH postdoc year 1 scale is impossible in certain places such as New York, San Francisco, Los Angeles and similar locations.

Proven or promising external resources or approaches

As above: change the pay scale to pay people what they are worth.

Response 1250

Perspectives on the postdoc roles and responsibilities

To me, an academic postdoc is essentially a preview to life as a PI. You get the opportunity to be much more independent than you were in your PhD and can now devote yourself solely to science. You are expected to drive/lead at least a few projects during your time as a postdoc, which should lead to multiple first author publications.

Fundamental issues and challenges

First and foremost, I think the elephant in the room affecting retention/recruitment is how underpaid postdocs are. You have a doctorate degree in your field, and for some reason are still considered a "trainee". Therefore, you get paid as if you are in training, when in actuality you are a highly specialized employee and should be paid as such. Almost all jobs have some degree of "on the job training" so applying this mentality to postdocs to justify low wages doesn't make sense. Furthermore, many postdocs are at the point in their life where they may wish to start families. Given the trainee status, you are afforded little to no benefits (retirement, childcare, ect) which could help off set the cost of the low wages while trying to start a family. Additionally, it would be remiss to not address the work culture of academia—combining severely low salaries with work hours that extend far beyond the 9-6 work day leads to not only an overall lower salary/hr, but a massive opportunity cost in terms of work-life balance. Treating a postdoc position more like a staff position would be the best way to even the playing field in terms of what non-academic careers offer. Lastly, I think postdocs get almost no training when it comes to what it takes to actually run a lab. When you are a PI, you stop working at the bench, whereas the majority of the postdoc is at the bench. It's a massive shift from PI to postdoc, and while you get well trained on the science, you don't get trained on the realities of leading a lab (financial budgeting, hiring/recruiting, how to start a lab, ect)

Existing NIH policies, programs, or resources

I like that a lot of these helpful resources are available, however, I think to fully understand them it might benefit individual academic institutions to implement workshops to discuss these policies/programs/resources with postdocs.

Proven or promising external resources or approaches

I think the working environment must be addressed. There needs to be a better work life balance in terms of what you see in non academic scientists positions. Mentoring efforts, training, and recruitment seem to be on a positive trajectory. I think postdocs today are offered more there than previous generations.

Response 1251

Perspectives on the postdoc roles and responsibilities

Postdoctoral training is considered the next step after graduate school on the path to becoming a professor. In the lab, a postdoc typically leads his/her own project while mentoring younger students. They serve an essential role in every lab and provide hands on mentoring because the PI is typically writing grants in his/her office.

Fundamental issues and challenges

It's very simple—they're not paid enough for the amount of work they have to do. More than 90% of graduate students in my department do not want to do a postdoc because the amount of time and effort simply isn't worth it. Industry positions allow us to pursue research without having to worry about being able to afford basic necessities like rent and food. It's embarrassing how little postdocs get paid for the amount of expertise and essential knowledge they provide.

Existing NIH policies, programs, or resources

Pay postdocs more. Increase number of grants and professor positions nationwide.

Proven or promising external resources or approaches

No response

Response 1252

Perspectives on the postdoc roles and responsibilities

I view a post-doc as additional training in project management, experiment design, analysis, writing, presenting, and navigating the publishing process. I also think post-doc positions can help you understand how academia works and what being a PI looks like. Post-docs seem to vary considerably. Some people have a never ending post-doc where they are really just doing research, but expected to do it faster and more smoothly than a graduate student. It also seems they are often expected to mentor grad and undergrad students whether or not they have training or interest in doing so. Some post-docs seem to act more independently, getting their own funding, driving a project and creating an opportunity to spin-off a mentor's work. There appears to be a lack of formal training. Certainly, some people take the opportunity to switch fields or join labs that use new-to-them techniques which certainly can make you more well rounded, but oftentimes, one seems to do something fairly similar and a substantial degree of know-how is expected when coming into the lab. I see post-docs as a means to secure cheap skilled labor to keep the biomedical research enterprise afloat. Labs that are post-doc heavy tend to be more active with high publication rates. I've seen post-docs really though who do not develop new skills, but just practice more of the same skills developed as a doctoral student (ie. carefully examining primary literature, developing protocols, statistics, manuscript writing, technical prowess). I see post-docs as a necessary evil for staying in academia or an academia-like setting (being a PI where you seek competitive funding). Some people use post-docs to boost their CV, publish, network, and get a better understanding of how to work the system in academia. Other people seem to just do research and straight research during a post-doc.

Fundamental issues and challenges

Academia is a highly toxic, competitive, abuse, trauma-causing system that rewards overworking, a lack of boundaries, and ego. Most people have a fairly negative graduate school experience and therefore graduates are leaving academia in droves. In my own PhD cohort of about 35, I know no one who wants

to stay in academia to be a PI. It doesn't help that the PIs we work for aren't raving about their jobs. Academia is also openly hostile towards minorities who are making up a greater and greater percentage of graduate trainees. But I can tell you as a queer, disabled woman, academia does not feel like a safe space. I will not pursue a post-doc. For a number of reasons.

1. I detest academia. It is run on exploitation, maintains a good-old boys club where misogyny, racism, able-ism and the like reign without scrutiny. There is no accountability for tenured staff regardless of how egregious their behavior. I have been consistently let down, made to feel inferior, and told implicitly and explicitly than I do not belong here (in academia) and will not succeed here.
2. I have to make money. I struggle to pay for groceries and healthcare. I have a dependent and cannot pay my monthly bills. I cannot continue to make insubstantial money. I want to be able to afford a car, a wedding, a dog. I can't post-pone making real money.
3. I value work/life balance. I am disabled and need breaks, rest, and time to decompress. It has been extremely difficult getting that in grad school and I know its harder as a post-doc. I cannot work 50hr+ weeks. I'm already burnt out. 4. The benefits do not outweigh the drawbacks. I want to work in industry. I can get a job without a post-doc

Existing NIH policies, programs, or resources

Increase pay and benefits. Shorten post-doc positions. There is a growing expectation that post-docs find their own funding. This is absurd given how competitive funding is. Encourage more organized post-doctoral training at universities (teach formal skills, support time for career development). Increase non-academic post-docs (co-op situation or academic/industry partnership). Reward institutions with shorter, more fulfilling (not productive) post-docs.

Proven or promising external resources or approaches

Treating post-docs like employees. Depending on the institution and funding source, post docs often are not employees. They are considered non-student trainees. As such, post-docs fall prey to the same vulnerabilities as grad students because they cannot come forward with issues, abuse, exploitation without fear of retaliation, career consequences, and being blacklisted. Post-docs often have less institutional support and resources specific to them. This makes them especially vulnerable to unrealistic demands from PIs. I know post-docs that work 80+ hour weeks and are here on weekends, holidays etc. It's not because they want to be here, its because their PI expects them to be there. If post-docs were treated as employees they would have legal protection from abuse, exploitation, and harassment. Currently, at many institutions, if a PI is unhappy with a post-doc for any reason they can make their life miserable, withhold letters of rec, or terminate their training. If they were employees they could use HR, they would have protections, they could point to specific rules for expected work hours, etc. Additionally, non-citizen post docs (international trainees and the like) are especially vulnerable since their ability to stay in the US legally is dependent on their post-doc status. Thus many international post-docs have no recourse or power in fighting abuse.

Response 1253

Perspectives on the postdoc roles and responsibilities

Further training to develop ideas and experimental approaches, to be a more independent researchers, to develop an additional sets of skills.

Fundamental issues and challenges

Wages, and ability to balance work and family life.

Existing NIH policies, programs, or resources

increased funding.

Proven or promising external resources or approaches

No response

Response 1254

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

The F32 application process encourages applicants to conservatively select a small cadre of study-section-approved, very senior full professors--who are almost all white men--as mentors, and discourages even slightly "risky" selection of younger, more diverse faculty who are scientifically outstanding and have excellent track records for someone of their seniority, but simply don't have the same mentorship track record as a 65-year-old. (One of our F32 applicants received criticism in her reviews that one of our outstanding midcareer full prof URM faculty with multiple R01s and many successful trainees did not have the expected mentorship track record, so this is not a hypothetical.) This perpetuates systemic racism and disproportionately discourages our underrepresented postdocs from pursuing the mentorship that best supports their careers.

Existing NIH policies, programs, or resources

Designate some F32 awards for mentees of outstanding underrepresented mentors, or at minimum clarify guidelines for expected mentorship track records for mentors at mid and late career stages.

Proven or promising external resources or approaches

No response

Response 1255

Perspectives on the postdoc roles and responsibilities

I'm a professional scientist, with the goal to obtain new skills as I transition towards my ultimate goal of entering academic as a tenure track professor. As such, my role is to develop and expand new skill sets, conduct novel & innovative research, actively publish my finding, and demonstrate my capabilities to acquire funding.

Fundamental issues and challenges

Money, money, and money. Post-docs are mainly held as a way-station as we transition towards tenure track positions. However, academia seems to be constantly raising their standards to achieve this endeavor. Publishing in Cell/Nature/Science is appearing to be the standard for faculty positions, however this gate keeps many qualified individuals. Furthermore, this can take years to outline the research direction, conduct the work itself, and go through the publishing/review process. This is time where we, as young post-docs, are delaying the start of our own academic path as a faculty member. And if tenure-track positions aren't your goal, then why stick around as a post-doc? You can get an industry position for 1.5x—2x the salary of the NIH minimum, which can still make it difficult to afford a house, raise a child/childcare.etc. The NIH pay-scale is not set to the cost-of-living of the cities that many universities reside, and as long as universities are allowed, they will continue to pay their post-docs the bare minimum set by the NIH.

Existing NIH policies, programs, or resources

Tie the NIH payscale for post-doc positions more closely to the cost-of-living of the cities. There are amazing institution out there looking for post-docs and advisors that are willing to pay them more, but are unable duo to internal policies tied to the NIH pay-scales.

Proven or promising external resources or approaches

Pay people what their worth. As academia raises the bar for faculty positions, the lengths of postdoctoral training increases to meet the increasing publication demands. We can only delay our lives (family planning, home ownership, career progression) for long before we just abandon it outright and look for positions outside of tradition postdoctoral training, where we are more fairly compensated for our expertise and skill sets.

Response 1256

Perspectives on the postdoc roles and responsibilities

From my perspectives and the advice I have been given, postdoctoral positions are most useful to people who are seeking to continue a career in academia or learn a particular skill that will enable them to transition to a position in industry.

Fundamental issues and challenges

The biggest challenge for me as I consider pursuing a postdoc is the disparity in pay between academia and industry. That, coupled with the intensity of the academic job market at the professor level, make choosing to postdoc in academia a relatively risky decision. You're going to spend several years getting paid little more than a grad student, and the prospect of finding a job after a few years as a postdoc is still limited. So pursuing a postdoc is in many ways a poor financial decision.

Existing NIH policies, programs, or resources

Stipulate that institutions desiring to receive funding from the NIH need to pay postdocs a reasonable, competitive wage.

Proven or promising external resources or approaches

No response

Response 1257

Perspectives on the postdoc roles and responsibilities

A postdoc in its current form is cheap labor to get data for a PI's grant. There is rarely training (despite being referred to as a "trainee"). NIH is not a reliable partner for postdocs given that they have developed and supported a system where postdocs are underpaid and serve at the mercy of their PI (who often has no personnel management ability). If a postdoc does end up with a faculty position, the process of getting grants favors established investigators so heavily that relying on NIH funding is essentially staking one's career on a dice roll given current paylines.

Fundamental issues and challenges

One of the biggest is clearly pay and it's remarkable (but not surprising) that this has not been taken seriously by NIH. Pay postdocs competitive salaries reflective of local cost of living and force institutions that accept NIH funding to provide all benefits like they do for other employees and you will retain them. Stop pretending that 30+ year old professional scientists are "trainees". These are the same people that are called (and paid like) Senior Scientist in industry. As such, NIH and academic institutions now have to compete with other fields given how far apart pay, benefits, and respect for basic human dignity are between academics and industry.

Existing NIH policies, programs, or resources

I spent 5 years as a postdoc and was supported by an F32 for 3 years. Getting my F32 was a bureaucratic nightmare and didn't even increase my salary. Apparently I was lucky because there were others at a sister institution that ended up having their salary effectively reduced after getting individual fellowships. Asking for huge amounts of effort to get a grant for essentially no payoff (one cannot eat "prestige") is nothing less than farcical and shows a major lack of respect for postdocs and their time. This system is in dire need of change.

Proven or promising external resources or approaches

After abandoning the idea of getting a tenure track position after a very successful postdoc, I did a 2-year fellowship dedicated to certifying PhDs as clinical laboratory directors. This fellowship funnels recently graduated PhDs straight into a well-paid and in-demand career, with job with placement of essentially 100% before they finish the fellowship. After seeing this system, doing a traditional postdoc where a single faculty member trains 10's of postdocs over their career, all of whom must vie for a small number of poorly paid, insecure faculty positions seems like an irrational decision. If a postdoc were more reflective of this type of training (i.e. high likelihood of a job with good pay after the fellowship), then there would be no shortage of applicants. If that type of promise can't be delivered on, then the current model of

academic science is not sustainable and will not serve a new generation of people facing extraordinarily high costs of student loans, housing, and overall cost of living.

Response 1258

Perspectives on the postdoc roles and responsibilities

As a recent clinical psychology postdoctoral trainee at an academic medical center, I viewed my training as an opportunity to gain

1) Mentored project management experience on NIH-funded trials;
2) Mentorship in grant writing in support of a K application; and
3) Supervised clinical practice hours towards clinical licensure.

Fundamental issues and challenges

While I began my postdoc planning to pursue a K award as a path towards independent research funding, I have since determined that I desire a primary clinical role as a professional. My primary basis for this decision was poor quality of life in academic research stemming from long work hours and porous boundaries between work and personal time. Academia places trainees in a vulnerable position in which they may easily be exploited by mentors due to the need for references and instrumental support to advance a research career. In turn, it is very difficult for trainees to maintain appropriate boundaries or work-life balance.

Existing NIH policies, programs, or resources

Academic research demands a greater share of one's time than most careers and entails challenging work and a highly specialized skillset. Without better salary incentives in exchange for these demands, many will be unwilling to pursue or maintain a career in academic research, especially in relation to available alternatives. Failing this, creation of better norms concerning workload would make a meaningful difference in retaining more academic researchers.

Proven or promising external resources or approaches

A model such as the VA's that caps trainee time at work could help significantly in terms of improving retention.

Response 1259

Perspectives on the postdoc roles and responsibilities

It is a job in science.

Postdocs keep being called a training opportunity—as a way to underpay and undervalue them) and while there is truth to this, any job on the market has to train a new person into the culture, IT, and institutional knowledge and may even take new employees that need quite a bit of training (e.g. like a fresh PhD or postdoc seeking new skills). And the new employee will get new projects. The difference is anywhere other than academia this person is properly welcomed, greeted, trained, and importantly PAID in salary and benefits.

Fundamental issues and challenges

SALARY—it should not be beneath $80,000 USD, period. It should be higher in higher cost of living areas. All medical (including infertility, maternity, and related care), dental, vision, retirement benefits (with matching), and childcare should be available and accessible (not backlogged) in first month. Vibrant postdoctoral associations should provide as much supplemental training, workshops, and community as those being given to graduate students.

Existing NIH policies, programs, or resources

Pay scale MUST be adjusted. NIH sets the standard universities look to. And it unfairly gives higher salaries to MDs who may not have any research experience over some PhDs, this should be thought through again, especially in the context of a postdoc that may have working/industry/other published or relevant experience.

SALARY—it should not be beneath $80,000 USD, period. It should be higher in higher cost of living areas. All medical (including infertility, maternity, and related care), dental, vision, retirement benefits (with matching), and childcare should be available and accessible (not backlogged) in first month. Vibrant postdoctoral associations should provide as much supplemental training, workshops, and community as those being given to graduate students.

Proven or promising external resources or approaches

NRC has high paying postdocs, perhaps some elements of how this is arranged could be useful knowledge for NIH. NIH has very high paying data science fellowships as well, perhaps mechanisms in this program can be of use.

Response 1260

Perspectives on the postdoc roles and responsibilities

I view post-doc as a bridge between the academic degree program and next career move. So as a post-doc, you may need to perform tasks ranging from scientific experiments, writing manuscripts and grants, mentoring, science communication, and some official duties. Because this is not a completely professional setting, there is no defined regulation on how post-doc training might go. Therefore, what is important is that your vision should align with the interest and aspirations of your PI and how you value the demands of your lab.

Fundamental issues and challenges

In my opinion, there are a few Fundamental issues and challenges: A, the availability of quality students with relevant training in the field. The majority of the US postdoc pool are immigrants. The overall quality of education and Ph.D. training in other countries have not improved to the US standard. So finding a good fit for the lab is quite difficult. B, There is a serious lack of mentoring/lab management skills in the majority of the mentors. This is especially true with the newer PIs. As a result, working environments in a large number of labs are toxic. I see a large number of PIs are extremely impatient, micro-manager, and lack a serious amount of moral and ethical senses. I believe that there should be an annual mandatory training and stringent regulatory system at the institutional level to improve the lab management skills of PIs. C. Another important issue is that a postdoc salary is not at par with a decent living cost/market value. So, I believe that relieving financial stress in postdoc tenure is a great way to attract brighter minds. Above all, a lab has to create a nurturing, supportive, and inspirational niche to foster great scientific discoveries and inventions.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1261

Perspectives on the postdoc roles and responsibilities

The postdoctoral time should serve as a period to develop new skills or questions after obtaining a PhD. The position should be guided by a faculty mentor, but more independent and collaborative, than the strict mentor/mentee relationship of a graduate position.

Fundamental issues and challenges

There are many, but chief are: Lack of a clear career path with few academic positions, indefinite length contracts, assumption of mobility/support structures to move repeatedly, assumption of health and the ability to work long hours, unclear paths for medical/family leave if needed, poor wages in high cost of living areas, two-body problems, toxic mentorships and over-reliance on reference letters as a path to career changes

Existing NIH policies, programs, or resources

Clearer pathways and better mentorship on non-academic careers, limiting the number of trainees a single mentor can take on through grant restrictions, better wage guidelines based on average COL

Proven or promising external resources or approaches

We need to be honest with ourselves that the entire pipeline of science is based on cheap, highly productive labor. The current rate that PhDs are produced is unsustainable without better and clearer career options. PIs are motivated to take on more trainees because wages and productivity/publication concerns incentivize large labs. Many postdocs choose to leave academic tracks at this stage because the realities of not being able to save for retirement, flexibly deal with health and family, or purchase longterm housing begin feeling unsustainable. Smaller labs, slower science, and longer, better payed contracts would greatly improve quality of life.

Response 1262

Perspectives on the postdoc roles and responsibilities

Postdoc is necessary step for an academic research career. It should be a period of learning from experts, having increasing independence and say in research direction, and developing your own independent research program. My PhD supervisors also emphasized the networking aspect. I would not recommend it for those pursuing non-tenure career path, though I am sure the skills may useful also for research scientists in academia and industry.

For us international people wishing to work in US, finding employment is also easier within academia than industry (J-1 and uncapped H1B visas).

Fundamental issues and challenges

I have greatly enjoyed my two postdocs, although in hindsight I feel I was more cheap labor than a trusted expert. My junior PIs did not show much interest in helping me develop my professional network or discuss my future, which certainly affects thoughts about my chances for faculty. There have also been no opportunities to obtain teaching experience.

I have decided that I would not even want my own research group. Work-life balance seems difficult to maintain, responsibility of having funding for a whole group seems heavy, and I am not interested in teaching courses. I would need better compensation than I see junior faculty making. Due to family I am also not willing to relocate after a job.

We’re a family of two postdocs and two small children without any support network in US. Childcare costs in SF are ridiculous, and university-affiliated childcare is among the most expensive. I am offended by our family not being eligible for back-up childcare (listed in graduate student and faculty benefits), since postdocs are lab workhorses. I got no paid parental leave as a postdoc (since I won a personal grant, was swapped to a paid-direct postdoc, and the foundation did not have a policy). We were saved by the daycare closures due to the pandemic (saving the fees) and enrolling our kids 3 days/wk, but I am sure it has left its marked on my work, relationship, and mental health. I am also sick of looking for the cheapest after school classes and holiday camps.

Most postdocs will not find tenure, and academic postdocs appear in industry as slow workers with dated skills. There is not enough open discussion and training on alternative career paths. Also support in faculty job search varies between PIs and departments.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1263

Perspectives on the postdoc roles and responsibilities

To me, a postdoc is a position to acquire additional skills and mentoring in preparation for academic positions

Fundamental issues and challenges

Issues with postdoc recruitment include a small salary, a difficult time moving for a short term position, and lack of academic positions following the postdoc.

Existing NIH policies, programs, or resources

Additional salary incentives and moving reimbursement to allow trainees to move more freely to desired positions.

Proven or promising external resources or approaches

The postdoc experience varies so much from person to person. It would be helpful if there was some sort of effort to ensure that people and issues don't fall through the cracks.

Response 1264

Perspectives on the postdoc roles and responsibilities

1. Establish research niche that you want to carry with you as a PI / gain new skills to carry with you as a PI
2. Mentorship

Fundamental issues and challenges

1. The poor salary and benefits compared to industry especially after being grossly underpaid as a PhD student
2. Lack of job security (unknown duration of time)
3. Lack of moving bonus—causes people to go into debt to move after PhD
4. No mentoring committee like a PhD student—aka only mentored by PI (this can go well or poorly)

Existing NIH policies, programs, or resources

1. Raise NIH minimum postdoc salary, allow PI to pay postdoc from whatever NIH grants
2. Allow moving bonus from NIH grants for postdocs
3. Scale pay based on city that the person lives in—please check out paper by Sainburg et al on this topic

Proven or promising external resources or approaches

I think that postdoc fellowships like the Schmidt Science Fellowship et al do a great job at not only providing higher pay to postdocs (100k), but also providing ACTUAL support. This support and training is severely lacking from universities.

Response 1265

Perspectives on the postdoc roles and responsibilities

It is a chance to improve the skills and get prepared for the future career. It is a time to work on the leadership skills, and how to communicate with other members of the team. It is also an opportunity to explore how the academic life would look like.

Fundamental issues and challenges

The biggest challenge we encounter is the salary is very low compared to similar industrial research positions, therefore, we are experiencing more difficulty in life especially when comparing ourselved to our peers in industry.

Existing NIH policies, programs, or resources

More connection to real industrial projects and higher pay

Proven or promising external resources or approaches

No response

Response 1266

Perspectives on the postdoc roles and responsibilities

Mentoring, driving independent projects, learning how to handle people and how to run a lab, writing grants and publishing.

Fundamental issues and challenges

Not provided benefits (retirement, paternity/maternity leave, child benefits, etc) and appropriate salary as other full time employees even though postdocs work longer hours than any other post. Because of this post docs usually have to suffer family life and/or proper self-care, which makes post docs feel less valued and ultimately moving out to the industry.

Existing NIH policies, programs, or resources

Provide better salary

Provide child care support

Provide retirement and other benefits like other employees

Provide funding to more people for moving to an independent early investigator position at an academic institution

Proven or promising external resources or approaches

No response

Response 1267

Perspectives on the postdoc roles and responsibilities

My idea of a postdoc is a "next step" beyond the PhD in the preparation for a career in research. Postdoctoral research appointments should have a blend of experimental activity as well as exposure to aspects of lab management, proposal preparation, and supervision. These skills translate to careers in industry, academia, and in many ways to science-adjacent career paths. Postdoctoral scientists should have some flexibility in time and experimental design/implementation. They should also be given opportunities to present/disseminate their work at conferences, as well as teach (on a limited basis) if academia is their path.

Fundamental issues and challenges

Cost. Between the cost of increasing salaries, increasing cost of health benefits that are absorbed by the PI/grant rather than the institution, and increasing cost of living, the ability to fund a postdoctoral researcher is more difficult than ever. Academic institutions are less and less likely to contribute to the support of postdoctoral scientists due to continued cost-cutting and finance-first models gaining prevalence in higher ed. This reduces the number of opportunities for postdoctoral hires. Yet, academic departments are becoming LESS likely to hire candidates without academic postdoctoral experience.

Existing NIH policies, programs, or resources

Require institutions to cover aspects of postdoctoral support. In my opinion, any institution receiving NIH funds should pay for the health insurance for all postdocs. Thus, no IDC would be charged on postdocs during budgeting. Institutions should also be required to develop concrete, institutional mentoring/support structure for postdoctoral trainees. There should be concrete expectations that some percentage of a postdoctoral trainee's time is spent doing non-experimental work (supervision, lab management, etc)

Proven or promising external resources or approaches

NSF, ACS, and other organizations run workshops to support "new" faculty. Those skills should be translated and introduced to postdocs.

Response 1268

Perspectives on the postdoc roles and responsibilities

We are asked to take on the role of staff scientist without the pay scale. Hours are long. It feels inappropriate since I have a degree and am not in grad school anymore, yet we are treated as glorified grad students.

Fundamental issues and challenges

I make the NIH minimum in a HCOL city. I have two kids, and can't afford daycare anymore for my youngest. I adjunct to make ends meet. I cannot afford to be a postdoc at this pay rate.

Existing NIH policies, programs, or resources

Please increase the NIH minimum salary. It needs to scale with COL. Inflation alone means that I earn significantly less than when I started.

Proven or promising external resources or approaches

Increasing pay and time off will improve retention. Everyone wants to leave for industry because of the money and the work/life balance.

Response 1269

Perspectives on the postdoc roles and responsibilities

A postdoc is a position after one has defended their PhD in which they put their knowledge they've acquired about how to be a good scientist into use by individually driving and executing experiments, while being severely underpaid for it.

Fundamental issues and challenges

I think the main issue is pay. After going to school for 30 years, postdocs still don't make as much as they would starting salary going into industry doing comparable tasks and having a better work-life balance. So, funding and time commitment are the main drivers in my eyes.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

Providing postdocs with the resources and support that comes along with a normal industry job, aka work-life balance respect, higher pay, retirement accounts, paid leave and family leave, health and dental insurance, etc.

Response 1270

Perspectives on the postdoc roles and responsibilities

Post doc is the last training position before looking for professorships or leaving academia and likely not being able to come back. It's also the last opportunity to dabble in something different and gain first-hand experience in something new yourself. Therefore, the postdoc position is very, very important in determining what kind of research one will continue to do for the rest of their life. Professors oversee things and learn things from a high level. They rarely do work themselves from my experience. Postdoc is the last time that one will work at a bench.

Fundamental issues and challenges

Recruitment & retention:

1. The pay, of course. Almost everyone will make more money if they go to industry instead of postdoc.
2. The high expectations of what must be accomplished during a postdoc to be competitive for a professorship somewhere (papers, papers, papers).

Quality of life: depends a lot on who the mentor is. A supportive mentor will make a huge difference.

Existing NIH policies, programs, or resources

The one thing that inhibited me a lot in academia is needing letters from people (reference, support, etc)! I get so much anxiety having to bother busy professors, having to keep reminding/harassing them to submit on time. I hate it and definitely skipped out on applying for funding opportunities because if it. And are these letters even useful? Everyone can find people who will write nice things about them. How does this set anyone apart? And if some reference does say something influential that seems to set an applicant apart, that could be a reflection on the reference, not who they are writing about. Lastly: did you know that more than half of the time, the professors ask us (applicants) to write the letters for them and they just sign off? Come on. Stop this nonsense requirement. It's inauthentic letters you all are reading.

Proven or promising external resources or approaches

1. Good pay and treating postdocs like a young faculty instead of like a more experienced grad student.
2. Starting in grad school, undergrad, or maybe even earlier, the academic path should be made less mysterious to people so that people who may otherwise not even know they would be interested—would have a fair chance to consider it. Do people on the street know what a professor does? They think professors teach at universities. Barely anyone knows that professors are scientists and their job primarily is to run a lab.
3. Workshops, classes, etc. that give practice with grant and paper writing, and also to teach us about how academia works in general. Examples: what can and can't grants be used for? What kind of funding is out there? What's a minimum publishable unit for a journal article? I know that there are website pages for some of this, but it's a lot of reading and no opportunity for questions this way. Also not everyone knows where to find all this info. In person is better.
4. Please please see my recommendation on getting rid of recommendation/reference letters. Industry does this better by not asking everyone to waste time upfront. Only at the end as a final "clear" for a candidate. Often on the phone instead of in letter form. Much less intimidating and less pressure on everyone. You can ask questions instead of hoping some letter addresses everything.

Response 1271

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

pay is very inadequate relative to responsibilities and other options with a PhD (eg. national labs, biotech industry). very little opportunity to make horizontal moves in case advisor relationship is not good, quite beholden to advisor for recommendation letter and networking in order to secure a more permanent academic job

Existing NIH policies, programs, or resources

Proven or promising external resources or approaches

Intramural investigators can pay postdocs so much more than extramural investigators. Can NIH better cost share between intramural and extramural programs to reduce the disparity between compensation of NIH-funded extramural and intramural postdocs?

"The discrepancy becomes even more shocking as postdocs gain experience and are compensated unequally for their developing skills and professional training: extramural postdocs can expect $66,000 after seven years of experience, whereas intramural postdocs can expect $105,750—nearly 50% more than the extramural stipend for 20227,12. In fact, the highest salary for an intramural postdoc in 2020 was $108,932 (Gary McDowell, personal communication)."

https://www.nature.com/articles/s41587-023-01656-4

Response 1273

Perspectives on the postdoc roles and responsibilities

It's a way for academic and corporate labs to leech work out of promising young scientists who deserve better, under the guise of providing them more training. This "training" is unnecessary and is an impediment to their early career growth.

Fundamental issues and challenges

Pay them more, you [redacted]ing dickheads.

Existing NIH policies, programs, or resources

Pay them more. Stop whining that workers are realizing you're paying them a quarter of what they should be earning.

Proven or promising external resources or approaches

PAY THEM WAY MORE MONEY.

Response 1274

Perspectives on the postdoc roles and responsibilities

I would never touch a postdoctoral position. I refuse to perform innovative and field-advancing research at a doctoral level for approx 50k. I would love the workflow and day-to-day of a post doc, however the compensation is absolutely ridiculous and I refuse to suffer anymore. I have already suffered poverty despite extreme stress and a demanding career for a decade.

Fundamental issues and challenges

The pay is abysmal, the work-life balance is awful, you are treated as a student pay and benefits-wise when you're 30-40 years old with 10+ years of experience. You are probably trying to start a life, potentially a family, and a career. I literally had a working relationship with a post doc that was in one of the most well-funded labs at my prestigious university who was supporting his family on food stamps. This is egregious.

Existing NIH policies, programs, or resources

Pay us.

Proven or promising external resources or approaches

Pay us.

Response 1275

Perspectives on the postdoc roles and responsibilities

A postdoc is the chance to continue to perform cutting edge science and further ones education.

Fundamental issues and challenges

There is a complete lack of childcare help. As a father there is zero incentive to do a postdoc when I can go to industry and earn 5x more. If Universities gave childcare some thought they may be competitive. I would take a paycut to do amazing research as a postdoc but in the current environment it is a negative on my children.

Existing NIH policies, programs, or resources

Learn that postdocs have families and help them pay for basic necessities.

Proven or promising external resources or approaches

No response

Response 1276

Perspectives on the postdoc roles and responsibilities

Program to advance in research activities, network with experts, publish high impact journals from quality research, mentor undergraduates and M.Sc students, present conference and position papers, contribute to policies. Initiate innovative research that can lead to patentable products, prototype desine commercialization, income, and development. Host institution contributes to revenue generation and maintain royalties for inventions. It is also a sort of employment to earn a living while contributing to science.

Fundamental issues and challenges

For women in Africa, family: The challenges of living your families, The husband may not be interested in supporting the wife

Undergraduate tndergraduate training curriculum does not open up the student to see beyond their current program and aspire to be a Postdoc as his or her career progresses.

At Masters level in Nigeria, Research are supported by personal and family funding, such the topics are not designed inline with priority needs of the society, to obtain funding, nor is the outcome aimed to be presented to relevant stakeholder. Thus continuety and sustainability of personal ideas is not maintained.Similarly, research by doctoral trainees are not supported in grants. In addition, there are limited inductrial training interphase.

Morover, there are no adequate training on how to write proposals and apply for grants from local and international organisations. In Nigeria, only recently are grant application incorporating the need of an M.SC, PhD and Post Doc opportunity.

The career progression at academic setting in Nigeria, requiure evidence of publication irrespective of weather it was personally funded or not and not really on postdoc experience. The academic system is not designed to employ post doc.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

Institutionalise Postdoc in African Universities. Add priority research topics to focus primarily on biomedical reseach problems peculiar to Africa. This would encourage research into such problems and promote local content. In that case the postdoc trainee would not need to travel abroad to cunduct quality researcg

Establish more centre of excellence with the modern technology, equipment and innovations to support biomedical research

Train senior researchers to be mentors and not tormentors. To think as a team player and not as a boss. Identify gifted and talented individuals and encourage their progresstion upto the need to continue with Post Doc. Great awarness on the interelationship between earning a living while working as a postdoc trainee.

Extend network and provide opportunities for undergraduate or graduated to see available postdoc opportunites, available career opportunities,and prospect from conducting biomedical research.

Outcome of research should not only be for scientific communities in areas where people are not focused on academics, thus information desemination to grassroot and parents and guardiance that pay for majority of off pocket—family sponsored academic research. Thus, they can encourage undergraduate to ensure their trainings are result orienting, targeted at rendering services to address human needs while making a leaving. They should also be well informed such that they can encourage their family menmers to focus and conduct research that would be well supported pto Postdoctoral level.

Response 1277

Perspectives on the postdoc roles and responsibilities

Roles: To leverage their prior training and the resources and expertise of the institution where they are in a post-doctoral fellowship to develop a niche area of investigation which they can focus their laboratory on. To enhance professional training—grant writing, working in teams, new scientific skills, and strategic planning.

Fundamental issues and challenges

Salaries are very low especially in expensive cities, which negatively impacts quality of life. There is also a perception that the career pathway that follows will be difficult to establish with high barriers to securing federal funding. These factors combine to encourage trainees to avoid post-doctoral positions or to do very shorts post-docs before a jump to industry.

Existing NIH policies, programs, or resources

Salary stipends for the T32 should be increase and reflect geographical challenges

Proven or promising external resources or approaches

No response

Response 1278

Perspectives on the postdoc roles and responsibilities

I view the postdoc position as an opportunity to gain additional training and mentorship to prepare me for a career in academia and to shape my independent research program. The responsibilities of a postdoc should include a combination of work on research projects run by the mentor as well as new projects that help facilitate the development of the postdoc's research agenda. In addition to training, the postdoc position should largely provide opportunities to publish and write grants with the postdoc as the PI. Given the brevity of most postdoctoral positions, an environment where the postdoc has protected time for research is ideal, with additional opportunities for professional development seminars, teaching, and mentoring depending on the goals of the postdoc.

Fundamental issues and challenges

Generally a postdoc position is designed to be fairly short and help move the postdoc to a full-time academic position. Because of the nature of the position, challenges related to moving, low-pay, low-benefits, and difficulty launching new projects can be barriers to a productive postdoc position. In my experience, poor mentorship, lack of data availability to carry out the research proposed, and low pay have been factors that have contributed to a postdoctoral position that has not been satisfying. I imagine that this would be similar for other postdocs and an issue when you are starting a position that you expect to last 2 years, but due to data delays and lack of mentorship support, the position can be longer or not as helpful for your career as expected.

Existing NIH policies, programs, or resources

I think pay, benefits, and community would help improve the postdoctoral experience.

Proven or promising external resources or approaches

No response

Response 1279

Perspectives on the postdoc roles and responsibilities

A job that allows you to publish more research to put on your CV prior to applying for faculty position.

Extremely demanding job that requires long hours.

Often requires mentoring and overseeing grad students and undergrads in lab.

Fundamental issues and challenges

Pay is far below industry standards, oftentimes below livable wages in areas with high cost of living.

In fact, might go so far as to say pay is insulting given the amount of training and experience a postdoc has, as well as hours put in.

Existing NIH policies, programs, or resources

Increase the salary to minimum 100k USD/year, at least in high cost of living areas.

Proven or promising external resources or approaches

Increase the salary to minimum 100k/year, at least in high cost of living areas.

Get over the ridiculous mindset that a postdoc is 'training'. These days, being a grad student is barely even 'training' anymore —undergrads and being an RA before being a grad student is the time when most people are trained.

Response 1280

Perspectives on the postdoc roles and responsibilities

The postdoctoral position should vary from postdoc-to-postdoc depending on their individual goals. For me, it is an opportunity to learn a new field and new techniques while moving toward greater independence. Well-supported intellectual freedom is a must for me to be happy in a postdoc.

Fundamental issues and challenges

The postdoc gives limited money (I could just about double my salary in industry immediately) and benefits (retirement savings!) while offering little up-side at this point. It should offer me greater intellectual freedom and a path to a career in academia, but if the path to the career in academia is too limited or the intellectual freedom is insufficient (my lab treats me like a talented technician or research scientist), there is no point in accepting that limited money and benefits.

Existing NIH policies, programs, or resources

My idea is that there should be available larger fellowships for mid-late postdocs (years 2.5-5) that give

a) increased salary and

b) salary for a postdoc to hire a single technician or post-bac, while the postdoc stays in their current lab, essential creating a sub-PI role for that postdoc.

It will give the postdoc greater freedom and responsibility, increased salary, and mentorship experience that will benefit them when running their own lab. I'm not sure if any programs currently exist like this.

Alternative ideas just include creating ways to increase salary and increase retirement savings/benefits. Postdocs should be contributing to social security and/or a 401K at this point in their lives.

Proven or promising external resources or approaches

No response

Response 1281

Perspectives on the postdoc roles and responsibilities

The postdoc is an opportunity for me to learn new skills and publish papers, so I can get a faculty position.

Fundamental issues and challenges

The pay and benefits for postdocs are barely livable. Postdocs have extensive training and education, but we're expected to survive on a fraction of what we could be making in non-academic careers. For example, all of my close friends who completed their undergraduate education with me are making at least $100,000/year. I'm making just over half that as a doctor. This is a huge hurtle for postdocs to overcome and makes the career trajectory difficult for all, and impossible for some.

Existing NIH policies, programs, or resources

The postdoc pay scale has to be raised. Postdocs should also receive employee benefits from their institutions. As a "trainee" we are caught in limbo between graduate student and employee. Unfortunately, we don't get the protections of a student, or the benefits of an employee.

Proven or promising external resources or approaches

The only way to improve recruitment and retention of postdocs is to treat postdocs as actual employees of an institution. With pay and benefits that reflect our skill level and our value to the institutions we work for. Everything else would just be fluff to distract from the major issue.

Response 1282

Perspectives on the postdoc roles and responsibilities

Postdoc position is a job in which a postdoc contributes to the overarching goal of the lab, institute, and to the research niche of their field. They are workhorses of how science keeps evolving. They simply cannot just be trainees. They are workers.

Fundamental issues and challenges

Low payment, lack of employee rights, and visa-related hassles are the big ones.

Low-payment is quite straightforward. Payment is low relative to industries. Postdoc payment is relatively worse in a high cost-of-living area. Low payment kills the attraction of postdocs by big time.

Lack of employee rights: NIH treats postdocs are trainees, which itself is discriminatory as the expectation for postdocs are that they work full time, do research, write a paper, grants and so on. In some places the expectations are even participating in a journal club and taking classes or seminars. One of the biggest challenge is that postdocs are not seen as employees and that cuts them from having employee rights. Because of the lack of employee rights, a postdoc position is very insecure and PIs tend to use this insecurity as a bargaining tool and justify exploitation of a postdoc.

Visa-related issues: There is very little mental peace among international postdocs because of the visa related issue--as they are in the cusp of being kicked put of the country anytime. J1 and F1 OPT visas are very restrictive and inhumane and arguably inhuman. The spouse cannot work, (on top of that the postdoc salary is low on itself), cannot do any side hustles that make money such as blogging or doing photography in your free time.

Existing NIH policies, programs, or resources

1) Recognize postdoc as full time jobs and have employee rights secured.
2) Provide strong visa-related support. J1 visas are very restrictive and it is time to change visa policy. Some of the visa policies like, you cannot do a freelance / side hustle, your spouse cannot work, etc are quite discriminatory and needs to be modified, or abolished completely. Another option would be advocate creating a visa system that removes hassles related to visa and gives mental peace that they are not in the cusp of being kicked out.
3) Increase the payment. Consider the cost of living of the area where a postdoc is doing her/ his postdocs.

Proven or promising external resources or approaches

1) Recognize postdoc as full time jobs and have employee rights secured. Have clear (and assertive) policies regarding paid leaves, maternal / paternal leaves, provision for retirement plans, sick leaves etc.
2) Provide strong visa-related support. J1 visas are very restrictive and it is time to change visa policy. Some of the visa policies like, you cannot do a freelance / side hustle, your spouse cannot work, etc are quite discriminatory and needs to be modified, or abolished completely. Another option would be advocate creating a visa system that removes hassles related to visa and gives mental peace that they are not in the cusp of being kicked out.
3) Increase the payment. Consider the cost of living of the area where a postdoc is doing her/ his postdocs.

Response 1283

Perspectives on the postdoc roles and responsibilities

It means transitional training, where an individual is trained to conduct research projects and other aspects of academic life. This includes training in grant writing, reviewing scientific papers, acquiring skills in state of art technology, and getting an opportunity for networking and oral presentation of the scientific work. It also means a certain degree of independence in conducting research and preparing for the next phase of academic life.

Fundamental issues and challenges

The fundamental issue in recruiting a postdoc is a low pay scale. For a fresh Ph.D. graduate suffering to meet their ends, an industry pay scale is much more lucrative than academic jobs, even though one is passionate about science.

The fundamental issue in retaining a person in a postdoc field is PI/mentor bias. Micromanagement, lack of independence, being too rigid in ways an experiment needs to be conducted, and not perceptive are a few examples of mentors who might force a postdoc to leave the scientific field unknowingly.

The overall quality of life of postdoctoral training can be improved by increasing the salary to a respectable amount and training the mentors to guide a postdoc.

Existing NIH policies, programs, or resources

NIH should strictly monitor PIs or institutions that pay salaries even less than what is written in NIH pay scale. Institutions don't make salary adjustments yearly, and even a 2nd or a 3rd-year postdoc is seen working with an old NIH pay scale with postdoc 0 salaries.

Proven or promising external resources or approaches

No response

Response 1284

Perspectives on the postdoc roles and responsibilities

Postdocs should act as assistant PIs. They are responsible for conducting independent research with less guidance from the PI than graduate students. They should help mentor graduate students in the lab as

well to practice trainee management for when they become a PI. They should learn about how the PI manages their grant funding and lab budgets and submit grants of their own.

Fundamental issues and challenges

If you go straight from undergraduate school to graduate school to a postdoc, you would be starting a postdoc around age 28. The average age for having a first child is 26. Many people put off having children in graduate school due to lack of time and money, but a postdoc is a more stable job where couples begin having kids. Postdoc salaries are not high enough to pay for childcare. The postdoc in my lab wants desperately to have a baby, but her husband is still in graduate school, and they don't think they can afford it. If someone is leaving graduate school and wants to start a family, industry with a higher salary and better work hours is the obvious path.

Existing NIH policies, programs, or resources

A stipend for childcare per child.

Proven or promising external resources or approaches

A stipend for childcare per child.

Response 1285

Perspectives on the postdoc roles and responsibilities

Our School recognizes that postdoctoral research fellows are trainees working in an apprenticeship mode in preparation for a career as scientific professionals. The mentoring provided to the postdoctoral fellow by the faculty mentor is critical to the fellow's career development and advancement. In addition, postdoctoral fellows are generally expected to function responsibly and autonomously within the School's complex and decentralized environment. Independent thinking and action are in fact requisite to successful careers in research.

Responsibilities of postdoctoral fellows include the following:

- Assume primary responsibility for the development of their research and career.
- Play an active role in seeking career and research advice, both from the faculty supervisor and from other faculty members as appropriate.
- Perform the research required by the faculty supervisor to a high standard and in accordance with all institutional and federal regulations.
- Participate in the postdoc career development and annual review process.
- Work in a collegial and cooperative manner with the faculty supervisor and other co-workers.

Fundamental issues and challenges

The biggest issues that are currently inhibiting our postdocs:

- Child care
- Cost of living in Boston area
- Salaries
- Industry has the ability to pay higher for new PhDs
- External postdoc benefits—cost of health insurance for self and/or family, salaries are less likely to be comparable to internal, and cannot afford cost of living in Boston
- International postdocs—immigration status and language barriers

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1286

Perspectives on the postdoc roles and responsibilities

My experience as a post-doc has been running projects for principal investigators that don't themselves have time to run their own projects they have committed to.

Fundamental issues and challenges

Many institutions do not allow postdocs to apply for grant funding as a PI. This means they have no way of showing they can obtain independent funding, or earning more money for their salary.

Another significant issue lies with the academic institutions. They are not creating permanent positions—mostly are adjunct contracts renewed yearly. Despite the ever increasing enrollment numbers they do not invest in faculty and teaching. So even if the financial difficulties of being a postdoc are manageable for a few years, there is not a financially stable career to look towards.

Existing NIH policies, programs, or resources

The limits on post-doctoral salaries and percent effort are inappropriate, especially given that they are not adjusted for differences in cost of living between different cities. The opportunity cost due to salary differences between academics and industry is upwards of $50,000 in certain fields. With economic instability, inflation and housing prices, staying in academics is not a reasonable choice.

I think that funding being spent on paying faculty that already have permanent positions to conduct "professional training" workshops is not a good use of resources. Those resources should be used to fund positions for post-docs and pay them a living salary.

Proven or promising external resources or approaches

No response

Response 1287

Perspectives on the postdoc roles and responsibilities

A post-doc position should be set in two different ways: an academic track or an industry track regardless of whether the post-doc does their role in an academic institution or industrial organization. However, the current issue is that academic post-docs are severely underpaid for the amount of work that they do. Why do a post-doc when you can work in industry and make more for doing the same amount of work? Not all companies have post-doc opportunities and they are severely limited to post-docs who can start in the summer of each year. In my opinion, the roles are no different no matter where you work. At the end of the day, a post-doc is an opportunity for one to broaden their research domain, publish more if they were not able to publish that much during their PhD, and network/collaborate.

Fundamental issues and challenges

The funding for post-docs, the NIH does not properly scale the minimum salary to the cost of living at institutions where you need to attend to be a successful post-doc. Cities like Boston, Manhattan, Chicago, Austin, or schools in California have some of the best post-doc programs which would be the only places to do a good post-doc. However, the NIH says that $55000 is the minimum salary which most faculty will not contribute higher towards to higher a post-doc? That is unjust and very negligible to one's quality of life. Some post-docs have student loans, how are they supposed to pay them off if they need to do a competitive post-doc and can barely live in a three-bedroom apartment? Same goes for retention, I am only doing a post-doc for now till I can get into the industry since I graduated when companies were on a hiring freeze and I needed a higher salary to pay my loans. But as soon as I find a job I am jumping ship from the post-doc and that is how it will be. Pay us more and maybe we will stick around or want to be recruited.

Existing NIH policies, programs, or resources

Increase the salary minimum or at least scale it by city. $55000 is not proportional across the US.

Proven or promising external resources or approaches

Look at the cost of living in various cities at the current rate of inflation.

Response 1288

Perspectives on the postdoc roles and responsibilities

A postdoc is essentially equivalent to the Journeyman/Wandergeselle in the medieval guild system.

We do the bulk of the actual research and manage most of the day-to-day affairs of the lab. Typically we have moved not once, but twice to be further employed in a temporary position for low pay with functionally no future job security. The prospect of "training" is an outright fabrication. We're cheap labor required to keep the machine running.

Fundamental issues and challenges

The NIH knows what the problem is already. It's pay. It's job security. You've known this for decades at this point. Asking the question again isn't going to provide you with some new magic solution to a problem that hasn't been thought of before.

If anything, the structural factors that have led to this predicament have only gotten worse since the last time you solicited feedback for these problems. Are there more or less universities and tenure track positions since you last asked these questions? Has the value of the dollar increased or decreased? Has the cost of living increased or decreased? Has the debt burden of PhDs increased or decreased?

Existing NIH policies, programs, or resources

Pay industry rates for PhD-level work. Industry does all of the job training and professional development the NIH provides, and they do that without using said training as justification for lower pay. If you seriously want the best and brightest working on NIH projects and advancing the mission of the NIH, you have to provide the same degree of pay and opportunity that industry does.

Proven or promising external resources or approaches

Pay people what they're worth and provide more avenues for long-term stability in people's lives. Upending your entire life and moving across the country over and over again for marginal pay isn't worth it to most people. If you want the best scientists and innovators, you're going to have to pay them what they're worth. Otherwise why wouldn't people look to industry? Why wouldn't they try to leave the country and move to somewhere that has more social stability and better working conditions? Why wouldn't they move to a place that facilitates raising a family better than the United States? If a PhD is worth what we say it is, these are precisely the people with the skills and means needed to leave the country, and from my communications with people early in their scientific careers, that is rapidly becoming the default plan.

Response 1289

Perspectives on the postdoc roles and responsibilities

An academic postdoc primarily fills the niche of providing the highly skilled labor needed for PIs complete aims outlined in their research grants. In most cases, an academic postdoc progressively gains additional administrative, grant writing/reviewing, and teaching skills needed to pursue their own independent career (as a PI) in biological/biomedical academic research.

Fundamental issues and challenges

The two biggest issues facing postdoc trainees in academic research, in my opinion, is the very low salary levels (especially compared to industry salaries) and low amount of independent, tenure track faculty positions currently available.

Existing NIH policies, programs, or resources

Removing salary caps for postdocs would provide PI's the freedom and flexibility to recruit and retain highly skilled postdocs (i.e. allowing the PI to set a competitive salary needed for the rigor of their own research). As we know, the roles of postdocs vary even within the same lab and we should allow more of a market based approach when determining pay. As for the lack of academic positions, NIH should place a term limit (a very liberal one) on grant funding for tenured faculty, freeing funding for younger postdocs, which ultimately would lead to academic institutions having more academic positions available for postdocs to join the faculty workforce. EXPAND LOAN REPAYMENT PROGRAM TO POSTDOCS.

Proven or promising external resources or approaches

All academic postdocs who receive NIH funding should perform a required annual (or biannual) questionnaire that can provide continuous feedback to the NIH on our concerns in the workforce.

Response 1290

Perspectives on the postdoc roles and responsibilities

A transitional and training role. Leading multiple research projects while acquiring new skills and improving on existing ones. New skills include both professional (ie new methods and protocols), personal (mentoring, leadership, collaborative work), and academic (grant and fellowship writing).

Fundamental issues and challenges

The pay is low, I have a family to provide for. Benefits are terrible, paying a lot of health insurance for my dependents. Definition of responsibilities is vague and my mentor and I struggle around that.

Existing NIH policies, programs, or resources

Minimum pay should be higher, to match the increase in cost of living. Role should be better defined, with proper institutional supports required for postdocs. Currently I feel like I have no job security and no safe guards in case I need them.

Proven or promising external resources or approaches

No response

Response 1291

Perspectives on the postdoc roles and responsibilities

Postdoctoral training means that it's a training and it could lead to a potential transition to a stable job after 2-3 years of postdoc. I think, the maximum period for postdoc training should be 2-3 years. Then, the positions should be transitioned to Assistant Professor Research and it should be compensated fairly.

Fundamental issues and challenges

First, salaries and compensations are extremely low considering the level of expertise and efforts it requires. The people in IT, with less qualifications, have higher salary in the same institutions with relatively less qualifications, responsibilities, and risks involved. At the end of the day we also have to pay the bills and expect decent living. People with family and kids are struggling to survive. Most of the universities and institutions pay the minimum NIH scale irrespective of the cities we live in and they cite NIH pay scale as their criteria.

Second, there is not much independence in the kind of the work we do as postdocs.

Third, as an international postdoc, most can't apply for many of the grants.

In short, Postdocs serve as CHEAP LABOR to most of the PIs and institutions, instead of growing as individual researchers.

Existing NIH policies, programs, or resources

1) Salary and grants should be revised in accordance with the qualifications and expertise. Also, it should include the provision of housing allowances according to the cost of the living of different cities. Rents in big and small cities are not the same.
2) It can't be denied that international postdocs are a major contributor to the research work in the US. International postdocs, working in the US labs, should be considered at par with the US citizens for the NIH grants.

Proven or promising external resources or approaches

First, however we try to justify but in reality postdoc is not training. It's a job. It should be compensated at par with that job requirements.

Second, most of the postdoc salaries come from the PI grants. It creates a difficult situation for the postdocs and makes the international postdocs vulnerable to exploitation by the PIs like long working hours, threat to fire from the job, less intellectual freedom. There should be a way where PIs shouldn't

feel that they are doing favour by hiring a Postdoc or they are the direct employer. There should be mandatory 3-6 months of compensation in the case of early termination. The postdoc should be notified at least 6 months in advance in written, if PI is unwilling or unable to support a Postdoc because of lack of funding or any other reason. This will make PIs more careful in hiring who they want and give postdocs flexibility for their transition.

Third, most of the grants go to the some very well funded labs because of the grant criteria. It gives little scope to others to grow.

Response 1292

Perspectives on the postdoc roles and responsibilities

Academic postdoc is an advance training time where individuals learn new skills and apply to progress in their career paths. In addition to learning, it also helps in overall personality development, boost up confidence and passion for performing productive research.

Fundamental issues and challenges

Fundamental issue is the SALARY!! They don't get enough to sustain in most of the cities. Some of the places like St. Jude have increased the salary of their employees tremendously after seeing the downfall in quality of life of post doc trainees.

Next challenge is to find jobs in academic career after doing post doctoral research.

Other challenges for foreign nationals include visa restrictions. A more flexible visa system should be implemented.

Existing NIH policies, programs, or resources

NIH payscale needs to be improved and more benefits to be given to individuals especially those who come from other countries. Most foreign nationals suffer because of less grants in academia for them when compared to US citizens.

Proven or promising external resources or approaches

Job postings can be put on social media websites such as LinkedIn, twitter etc. Working system is hard to predict as it depends on Principal Investigator. A review based system can be started for ranking PI,s lab environment and working culture where ex-employees can give reviews anonymously.

Response 1293

Perspectives on the postdoc roles and responsibilities

As a postdoc I should have the freedoms to just do my science. I am past the trainee stage of a graduate student, but should not have all the administrative tasks of a PI. I feel the postdoc time is really the only stage in your career where you have the knowledge and the time to just explore scientific ideas.

Fundamental issues and challenges

As I mentioned in my previous response "I feel the postdoc time is really the only stage in your career where you have the knowledge and the time to just explore scientific ideas." However that is not my experience. I am often tasked with doing administrative things for my PI and filling the role of a lab manager. I am tasked with training graduate, undergraduate, and high schoolers at the cost of my own science. My PI often remarks "if you want to become a PI you will have to learn to manage your time". However, if I was free to manage my time I would not take on so many students that need their hands held the entire time. I am not paid enough to work 9-5 on training other people and keeping the laboratory running for my boss to then have to do my own science after 5pm all night long as my boss suggests. I deserve to have some amount of quality of life.

Existing NIH policies, programs, or resources

R01s, R35s, and other grants for PIs should increase in budget so that postdocs can be paid more AND PIs can hire more people. If PIs are forced to pay higher salaries without an increase in budget all it will do is

cause them to hire fewer people. Increasing the amount of other work postdocs are required to take on that take away from their research.

Proven or promising external resources or approaches

Recognize and respect the roles postdocs play in science.

Response 1294

Perspectives on the postdoc roles and responsibilities

A bridge between graduate school and pursuit of a position as a professor, a post-doc is set up to give recent graduates and opportunity to learn more independent project management and leadership skills. It is also an opportunity to gain new knowledge and skills in a different field, using the tools acquired during graduate training.

Fundamental issues and challenges

While there is freedom in choosing what you may work on, the pay is not competitive with other post-graduate school jobs. It seems the only real reason to go into a post-doc is if you want to be a professor. There are even more limited numbers of professor positions available, and on top of that research funding and salaries from grant funding are not keeping up with current inflation rates. On top of that, it is typical in most labs to have an unhealthy expectation for work hours, making a work life balance and prioritizing health very difficult. While some mentors may not fit the typical academic culture, the majority are not understanding.

Existing NIH policies, programs, or resources

I am not as familiar with the options in this space, so I cannot comment.

Proven or promising external resources or approaches

I think that working environment and mentoring perspectives that see a post-doc as a human, not a pay line on a grant are key.

Response 1295

Perspectives on the postdoc roles and responsibilities

A postdoctoral position is an opportunity to become more independent, learn new and diverse skills, and develop ideas and possibly initial data for forming your own lab. To become more independent, you will propose new and original research ideas to your mentor, manage graduate students, and pursue a project that could be of your own design depending on the position. To learn new skills, you might broaden your expertise by accepting a position that isn't directly in your field. To work towards your professional development, you might begin to think of or acquire data that can support your desired faculty position, apply for grants, or network.

Fundamental issues and challenges

The biggest thing that would stop me seeking a postdoctoral fellowship is money. ~50% of postdocs in the US make less than $50,000, and this coincides with large life events like moving cities or states, starting a family, paying off student loans, and taking care of aging parents. There is essentially no way I could afford to take a postdoctoral fellowship for this amount.

Additionally, quality of life for postdoctoral scholars seems fairly abysmal, with no guaranteed time off, sick leave, etc., worse health care than a graduate student may have, and increased expectations with little increase in pay.

Existing NIH policies, programs, or resources

Minimum pay for postdocs >$60,000, standards for living including subsidized child care, sick leave, and PTO.

Proven or promising external resources or approaches

No response

Response 1296

Perspectives on the postdoc roles and responsibilities

A position in which a person prepares to be an independent research scientist. A postdoc should complete a project with more independence than one necessarily experienced in graduate school, learn widely from other disciplines, and apply to research funding for their future lab.

Fundamental issues and challenges

The NIH pays too little. That is it. At a time when people should build for their future (e.g., IRAs, buy a house, stocks), or be able to pay for normal events at that stage in their lives (e.g., mortgage, childcare, help elderly parents), they are not able. Those with wealthy families can better weather these finances than those without.

Existing NIH policies, programs, or resources

The major problem is that the NIH underpays postdocs. Though there are expected raises, the baseline is too low; it should increase to ~70k. My school—JHU—follows the NIH model, as do others I suspect, and will pay the minimum amount allowed by the NRSA.

One other concern is that I, as a fellow with an NIH grant, cannot get more money for my salary from my mentors' NIH grants. Since the NIH is a major funder, this limits my salary. However, even if this policy were lifted, there is no guarantee that my mentors would pay me more. Thus, the best solution is to increase the baseline NRSA salary. Perhaps, when PIs design a budget for R01s, U19s, or other grants, they should get a bonus to pay for the postdocs.

Proven or promising external resources or approaches

Industry pays ~twice as much.

Response 1297

Perspectives on the postdoc roles and responsibilities

I believe the postdoctoral role *should be* a brief (2-5 years), one-time training period where one gains additional skills and mentorship, particularly in grant-writing, project design and management, and mentorship of their own, before transitioning to an academic role. I also believe that it should be an opportunity to lay groundwork for one's own initial academic research program.

However, I think that in practice, postdocs are often longer and come in multiples, including roles that officially are not classified as postdocs but work as such in practice, and that trainees too often are locked in such roles or shunted to non-tenure track roles; and that many labs provide less mentorship to postdocs and more see it as an additional period of labor.

Fundamental issues and challenges

1) Low pay and benefits. This is a problem across academic training roles, but is particularly egregious at the postdoctoral level, when one has supposedly completed their main scientific training and often has additional family expenses, but is still being paid far less than comparable non-academic roles.
2) Only really a shuttle into academic careers. Academic postdocs seem generally to be viewed as a disadvantage for non-academic roles, so there is no reason to enter unless you want to go into academia—where everyone knows that tenure-track jobs are hard to get and only getting harder, and non-tenure track jobs are unsustainable and exploitative
3) Broader problems with the academic mentorship system; e.g. low pay + an "apprenticeship" style system that leaves trainees at the mercy of their mentor, who may be outstanding, but could also mediocre or outright problematic once you join the lab.
4) Increasing duration and number of postdocs. It's a much harder sell to swallow 2-5 years of low pay than it is 10 years with multiple moves, especially when you're still almost guaranteed *not* to get a tenure-track job, the only reason to take a postdoc, afterwards.

Existing NIH policies, programs, or resources

Increasing NIH minimum pay, since it is widely seen as the de facto actual rather than minimum.

Increasing the number of funding opportunities available to postdoctoral fellows, to allow more opportunities for individuals to show they can secure grant funding earlier in their training.

Stricter systems to ensure that professional ethics in mentorship and treatment of postdocs are followed, rather than an honor system implemented by those these guidelines are meant to protect postdocs and other trainees from.

Guidelines on how long a postdoc should be and what sort of roles are acceptable after, to prevent "research scientists" and other full-time research positions that are used as a way to extend postdocs to 7, 10 years or even longer with no appreciable outcomes for the postdoc themself.

Proven or promising external resources or approaches

Not a specific statement, but finding a way to transition the postdoc into a position that is appealing to both academia and industry would likely help retain people who might otherwise have left academia because the postdoc was "useless," which is beneficial not just in postdoc retention but in considering that very high barriers exist for trainees to return from industry and re-enter academia.

Response 1298

Perspectives on the postdoc roles and responsibilities

A postdoctoral position is a progression of scientific process through which individuals become independent investigators. The goal of the postdoc is to continue gaining laboratory skills in your field of interest, but training should focus mainly on how to develop testable hypotheses and curating independent projects. Whether the end-goal of the postdoc is academia, industry, or an alternative career this training is beneficial to the critical thinking process. Additional responsibilities for a postdoc include mentoring junior scientists (undergrads, graduate students etc.), writing manuscripts and participating in the peer review process, testing thought-provoking hypotheses, communicating scientific results, and writing funding applications.

Fundamental issues and challenges

Postdocs in academic positions are underpaid. Postdocs also have limited community in academic positions for several reasons:

1. postdoctoral stipends are a large percentage of a grant application budget, therefore labs are limited in their ability to hire postdocs, which hinders community among peers
2. there is a lack of structure within the academic system for postdocs—limited oversight beyond your direct supervisor, departments that spread across campus, few opportunities to interact with peers within your department, no dedicated administrative personnel for postdocs.

A lack of structure also leads to additional issues in training and mentoring whereby postdocs don't have avenues for correcting issues with their supervisor effectively stunting their training or forcing them to leave their position. An additional issue arises when mentor expectations exceeds what is reasonable for proper work-life balance. Mentors in academia have little opportunity and no requirement for training in mentoring. Some mentors have no desire but most have no recourse to better their mentoring styles to be more inclusive or accommodating to postdoc struggles with family life, stress management, mental health, or issues of diversity and equity. With the increased recruitment of newly graduated PhDs into industry where the pay is higher, the work-life balance is more appreciated, and the structure is well-implemented, there is little incentive to be an academic postdoc beyond a love of science and the postdoctoral requirement for academic positions.

Existing NIH policies, programs, or resources

Dedicated programs to training mentors that are readily available, are not cost-prohibitive, and are based in principles of equitable teaching and learning. Increased budgets for postdocs and additional trainee grants. Incentives to universities that prioritize postdoctoral training.

Proven or promising external resources or approaches

No response

Response 1299

Perspectives on the postdoc roles and responsibilities

Post doc is a time to gain confidence as an 'authority' in the field and learn new perspectives/fill gaps in knowledge left by graduate program.

Fundamental issues and challenges

Cost of living!!!!! I live frugally but still have to maintain a second job to cover my 'extra' expenses (i.e. clothing that I haven't purchased for 5+ years because my graduate stipend didn't cover enough, basic gym membership, date night out 1-2x a month). I plan to have a child in the next year and have no idea where the money for childcare is going to come from. With a PhD, I should not have to worry about covering these basics. A stipend that covers subsistence living (roof, basic food, vehicle) is simply not proper compensation for our skill level. If I didn't love my project and have a wealthy family I would have left academia as soon as I received my PhD. If we want to keep people in academia, we need to increase the stipends available.

Existing NIH policies, programs, or resources

Not sure because I am unaware of many of these programs. Perhaps better advertisement is currently more important than expanded programs.

Proven or promising external resources or approaches

pay your researchers!!! A fellow postdoc succeeded in receiving an F32.and his pay went DOWN. He could not continue supporting himself on that funding. Do better.

Response 1300

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

Reasonable salaries.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1301

Perspectives on the postdoc roles and responsibilities

When I began my postdoc training 4 years ago I thought that this position was intended to provide me additional training to become an academic PI, or to continue developing skills transferable to careers in industry etc. I took the known hit to salary because I wanted to do science in an environment that was not profit-driven.

Fundamental issues and challenges

For me, money and the state of academia.

1) Money, because I can't afford the medical costs of family planning (no fertility benefits) on a postdoc salary. Then after that I wouldn't be able to afford childcare.
2) Why do folks want to be in academia? Some—to do science. To be in control of their research direction. Some people will take a hit to salary, etc in order to do that. Those that can—ie do not have families to support, don't have debt, etc. It is easier to justify the hit to salary and benefits if the system is one that supports academics in the honest pursuit of knowledge. Instead, there are pressures that impact quality of life in that system: a publish or perish culture, top-down hoops to jump through to have research proposals accepted, work life balance deprioritized, policies that protect the university and not the researchers, questionable scientific integrity and minimal evidence of efforts to improve. That isn't tempting. I can work for an industry corporation doing science like this and get compensated appropriately for it.

Existing NIH policies, programs, or resources

Grant "awards". It is extremely frustrating to put in the work of writing a grant like an F32, receiving that award with applause, and then finding oneself no longer technically considered a university employee with significant negative consequences. Not only does this affect health insurance, workers compensation, access to university services and administration that understands my position, I also lost my retirement account—the first that I've ever had (beginning at the age of 31), having been in the academic system the majority of my adult life. Why are we punishing graduate students and postdocs who receive these awards by removing support?

Proven or promising external resources or approaches

Complete overhaul. Let's have an honest discussion about what postdocs are/should be. If it is a short (under 2-3 year) training position intended to lead to a senior scientist position in academia (one that is worth the short-ish term hit), during which the person knows they will be underpaid and unsupported but at least the trajectory is clear, then lets say that. If its a researcher position in an academic lab led by a PI, with some but low chance of leading to also becoming a PI, then make it an attractive position. Pay your workers. Give them rights. Otherwise of course they are going to leave and get paid in industry.

Response 1302

Perspectives on the postdoc roles and responsibilities

By the end of my postdoc I was able to develop my own independent research projects and my postdoctoral mentors switched role from mentors to collaborators.

Fundamental issues and challenges

Salary. As more and more graduate student unions are lobbying to increase pay for graduate students, the same needs to happen for postdocs. The NIH annual postdoc salary is only a $10,000 more than the (union negotiated) graduate student salary at the institution where I now teach—in fact it is well known in my department that hiring a graduate student is more expensive than a postdoc once benefits are factored in. This does not make any sense, especially when postdocs with biomedical backgrounds can earn 4X these salaries in industry. While a postdoc position is a training position, we also need to reward the skills postdocs have developed from their prior training.

Existing NIH policies, programs, or resources

Increase NIH salary for postdocs—my academic department pays postdocs on the NIH scale and it is hard to lobby from within to increase salaries. Provide paid support for postdocs on maternity/paternity leave—and let this support last closer to 6 months as opposed to 6 weeks.

Proven or promising external resources or approaches

Salary increases.

Response 1303

Perspectives on the postdoc roles and responsibilities

I am curious by nature and have a passion for mentoring, which is why I recently started a postdoctoral position to try my hand at a career in academia. I chose a position that will challenge me intellectually and help me grow scientifically, while also allowing me to learn the ropes of being in this environment under the mentorship of an excellent PI. That being said, I know there is no guarantee of my plans working out. I want to inspire young immigrants like myself to chase after hard problems, but I refuse to do so if it is financially unwise and emotionally taxing. I have given myself a 2 year deadline to see if I have a chance to become an assistant professor. After this deadline I will choose a job that will compensate me commensurate with my skill levels—skills that I have picked up in my PhD and during my postdoc.

Fundamental issues and challenges

After many conversations with friends and colleagues, I believe that postdoctoral positions by virtue of being defined as "trainee" positions, pay a lot less than a regular job. For most individuals living in a capitalist society, having a terrible-paying job with limited support from advisors, long hours, and simply the intangible ideal of making an impact are not alluring benefits. The rhetoric of "doing science in dingy laboratories no matter the cost to personal lives" is one akin to that of "the starving artist". It is completely impractical, and was perpetuated by a long-standing history of men in white coats before women were allowed in the workforce in any real capacity, and by individuals with family wealth to rely on.

If recruitment and retention of postdoctoral scientists is truly the goal, then a pay at least attempting to compete with industry standards, support from individual PIs as well as institutions towards the physical and mental well-being of their employees, actual rights as employees (paid time off, sick leave, etc.) along with the respecting of these boundaries would be the bare minimum as coming from the government. Finally, I hear that postdoc experience does not really count towards work experience in industry—a way to mitigate that would either be to encourage postdocs to pick up skills relevant to industry, or the government to create jobs within the academic framework that allow postdocs to transition to if the role of tenure track professorship is out of the question.

Existing NIH policies, programs, or resources

I have limited experience with the NIH policies and programs. However, I do believe that a more transparent grant review structure would greatly benefit many postdocs who want to stay on the academic track, especially the ones transitioning into PI roles.

Proven or promising external resources or approaches

Once again, limited experience with these. Possibly the dissemination of these resources to new postdocs as well as PIs.

Response 1304

Perspectives on the postdoc roles and responsibilities

opportunity to do more independent research that i am interested in and have the ability to navigate mostly independently. chance to go into a new line of research of interest

Fundamental issues and challenges

not enough money. as well as length of time required for a successful postdoc. limited faculty positions and how competitive it is. the "trainee" aspect: a grad student is a trainee, a post doc less so.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1305

Perspectives on the postdoc roles and responsibilities

I see postdoctoral training as a crucial step towards a mentorship/leadership role in conducting research, where one transitions from conducting research independently to sharing experience with young researchers. At the same time, this is a transitory period where collaboration increases among a wider breadth of knowledge. Finally, I see this period as the end of the decision-making process, where it still allows for pivot in your desired field (and choosing between academia/industry).

Fundamental issues and challenges

Especially in the states, academic burnout (and medical-field related burnout) are very prevalent. Securing funding into the postdoctoral position and maintaining it moving forward to either a senior researcher position or tenure-track faculty position adds to this. In addition, the timing frequently overlaps with other priorities (starting a family, settling down, etc.), and the majority of postdocs I interact with socially voice reasons for leaving as either financial or emotional reasons. In the biomedical field, there are so many startups that are more appealing financially than academia, where I see many swap over as adversity arises.

Existing NIH policies, programs, or resources

I think mental health and development of a strong academic support system is very important during postdoctoral training. Perhaps more resources or opportunities to interact with peers outside of direct lab space would be beneficial for growth during this period. With this, I think also having some template of different paths or speeds that you can work through your program with would be beneficial. In essence, being transparent on how the process has been tackled previously, either at a slow 'take-your-own-speed' pace, or accelerated 'accomplish a lot in a short amount of time' pace.

Proven or promising external resources or approaches

In all, I think increasing the frequency of meetings or get-togethers throughout the academic year would be beneficial. Many of the intersecting fields that make up biomedical research have unique timelines, and by having more opportunities to unplug, there can be accommodations for everyone.

Response 1306

Perspectives on the postdoc roles and responsibilities

I view a post doc position as basically trying to re-complete graduate education on a compressed timeline because there's no rotations, classes, etc. that grad students have to deal with and the post doc should be independent from the start and need minimal training from the investigator to do the project

Fundamental issues and challenges

THE PAY! For someone with the highest educational attainment possible, the pay is awful. Bachelors degree graduates can get jobs that pay more than a post doc with 5-10 years LESS experience and training. Why would someone, particularly in a struggling economy, go to work as a slightly higher paid graduate student for 2-5 years for half the pay of someone in industry or government position?

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

Improving postdoc recruiting would help! I think it's hard for graduating students to have the pressures of finishing along with trying to find a post doc and how to do it and when to do it.

Response 1307

Perspectives on the postdoc roles and responsibilities

An academic postdoc should be able to handle multiple projects and oversee training of younger members within a lab. They should be able to independently write papers and submit grants to fund their research. Generally, a postdoc should be able to do everything a PI can but to a lesser expectation of quality.

Fundamental issues and challenges

Postdoctoral trainees are grossly underpaid. Keeping in mind that a postdoc is seemingly an extension of a PI (expected to be independent on multiple projects, train younger lab members, submit funding, etc.), postdocs should be compensated more for their expected performance and usually longer working hours. Additionally, since postdocs are expected to work so much, and are under-paid, a career change to industry is often valued. By leaving academia, postdocs can now make much more money and work reasonable hours all while getting do do the science they are passionate about. To retain and recruit more postdocs, salary must be competitive with that of industry positions.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1308

Perspectives on the postdoc roles and responsibilities

I think of a postdoctoral position as a necessary step towards professorship. It is an opportunity to gain leadership as well as even more research experience. However, postdocs should already be able to independently conduct research work, with general oversight of a PI but without day to day supervision.

Fundamental issues and challenges

One issue could be thinking about postdoctoral position as a chance of last resort for graduates who did not manage to secure a higher paying jobs for example in the industry. I think that in many cases this can result in retention of less motivated researchers in academic labs. Unfortunately, one of the most fundamental issues in postdoctoral training is the unreasonably low compensation. Postdocs should be treated more as trained and competent scientists who only need to perfect some of their skills and not as students in an extended PhD training program. This should be reflected in higher financial compensation as well as more clear and regulated rules for work time. I think that unlimited work time policy leads to exploitation of postdocs by their supervisors/mentors at least in some cases.

Existing NIH policies, programs, or resources

NIH guidlines regarding minimal postdoc stipend/salary per year dependent on years of experience should be updated. In my opinion the amounts should be at least 50% higher than they are currently. It also would be a good idea to adjust them to the cost of living in the area where the postdoc would be places—Boston, New York, San Francisco areas with major research institutions have much higher cost of living than most other places in the country. I would also suggest considering regulation of the postdoc work time in order to protect postdocs from exploitation.

Proven or promising external resources or approaches

No response

Response 1309

Perspectives on the postdoc roles and responsibilities

Highly skilled individual that works semi—or completely independently to carry a research project from start to finish.

Fundamental issues and challenges

Post docs are not paid enough money. The age range of post docs falls within a particularly vulnerable time, where many, especially women, are also building their lives at home. Salary, more than anything else, can help promote a stability, and ultimately retention. For example, initiatives like the NIH childcare supplement, were instrumental to finding relief from the constant financial pressures in this role.

Existing NIH policies, programs, or resources

Support for individuals financially is the biggest issue that I can identify. It goes without saying that a post doc is a very motivated passionate person. They have to be to get this far. Pay them for these skills. An entry level job in almost any industry profession likely doubles pay.

Proven or promising external resources or approaches

It would be nice to not only have academic hierarchy as the final outcome as a postdoc. Can there be grants or training for developing research scientists? Many post docs would not mind staying as supporting role, but typically the only option is to level up to an assistant professor. At that point you need to run a small artisanal business. If there could be a stable alternative recognized by the NIH, that would probably retain many highly skilled, elder post docs that enjoy their job and don't really want to go onto the endless academic ladder.

Response 1310

Perspectives on the postdoc roles and responsibilities

Continued training toward independence. honing,as well as acquiring new, skill and traits. Working with candidate (frequently) to meet their career aspirations.

Fundamental issues and challenges

Costs of living; Feeling of disconnectedness (unless the local program, department, division, institute, explicitly addresses this); Imposter syndrome, especially if we advisors do not convey all that we like, value and benefit from in academia.

Existing NIH policies, programs, or resources

Proven or promising external resources or approaches

Many Professional Societies provide webinars, panels, career counseling, advising (SFN, ASCB, GSA., etc, etc). Society dues could be paid by NIH.

Response 1311

Perspectives on the postdoc roles and responsibilities

A postdoc position should be a training position that enables a scientist to transition onwards to a tenure track position.

Fundamental issues and challenges

Poor pay and precarious positions. I know multiple people who have been in high pressure scenarios to fund their own position lest they be forced to quit or work without pay.

There are not enough faculty positions for the number of postdocs seeking them.

Too long of training times, the post doc is ever expanding in time. It asks people to put off parts of their lives that their non-academic peers are able to enjoy.

Existing NIH policies, programs, or resources

Moving away from post-doc positions into more staff scientist positions for people who want stability and fair compensation but also want to contribute to academic science.

Proven or promising external resources or approaches

No response

Response 1312

Perspectives on the postdoc roles and responsibilities

Postdocs have PhDs and are still referred to as trainees by the NIH. They are a few years away from taking a faculty position and underpaid, overworked, and undervalued. The role of a postdoc is to be a

mentor to graduate students and do all of the things a faculty member does with significantly less money. It means spending more of your life in a difficult position.

Fundamental issues and challenges

The main issue is that postdocs (and graduate students) are underpaid. The NIH starts postdoc salaries at $56k. Postdocs have ~10 years of education and ~5-6 years of experiences and are being paid a paltry entry-level salary. Postdocs are at least entering their 30s, and many have or are planning to have children, yet are paid little and given substandard benefits. Further, postdocs are vulnerable to exploitation by PIs who are motivated to keep highly skilled personnel in their lab. Any other position would pay more. It makes no financial sense to pursue an academic postdoc unless family or a spouse is able to support the postdoc.

Existing NIH policies, programs, or resources

Graduate students and postdocs must be paid more.

Proven or promising external resources or approaches

Pay people more.

Response 1313

Perspectives on the postdoc roles and responsibilities

I was a postdoc for 2 years before leaving for industry. To me a postdoc felt like a continuation of graduate school. There were really no new opportunities presented to me that weren't also presented in grad school.

Fundamental issues and challenges

I chose to leave my postdoc because I felt undervalued. I was only making $10k more per year than the graduate students in my department, and was making less than many of my peers working in other fields who only had bachelor's degrees. After being a poor graduate student for 6 years, I don't think many people want to continue to struggle financially, especially if they feel like the postdoc isn't adding any value to their lives. If you don't want to be a professor, there is little value to a postdoctoral fellowship. Furthermore, the professors in my department didn't treat postdocs as any different than grad students. I felt like my degree and years of work/experience in research meant absolutely nothing in my postdoc.

Existing NIH policies, programs, or resources

Better pay for postdocs. More training opportunities that don't just rely on your advisor. Advisors sometimes seem dedicated to training, but once youre in their lab that's not the case. It would be nice to have external opportunities as well, especially ones that don't require money.

Proven or promising external resources or approaches

No response

Response 1314

Perspectives on the postdoc roles and responsibilities

The academic post doc is independently driving a research question and is training to become an independent researcher who leads other researchers in furthering a scientific field.Their responsibilities include conducting experiments, leading meetings, making collaborations and connections, managing projects and people.

Fundamental issues and challenges

The lack of funding for postdocs and the perpetuation of toxic PIs which drastically reduce retention of postdoctoral talent is a real issue. The postdoc doesn't get paid enough for the cost of living in cities especially compared to their peers in private sector.

Existing NIH policies, programs, or resources

Expand resources for funding postdoctoral researchers. Expand programs which support new PIs and Postdocs

Proven or promising external resources or approaches

No response

Response 1315

Perspectives on the postdoc roles and responsibilities

It is meant as a launch pad for a career in biomedical sciences. It is a labor-intensive phase of one's career and filled with ups and downs, both in professional and personal events.

Fundamental issues and challenges

No training in people management, soft skills, communication, budget management, public speaking, writing, non-traditional careers. Low pay. Resources are concentrated in the NIH intramural program, which is too elitist and bureaucratic as a career choice.

Existing NIH policies, programs, or resources

Higher pay, more training opportunities, regular and formal progress evaluations.

Proven or promising external resources or approaches

Programs with FDA, training fellowships that allow them to work in places other than NIH. Expanded access to NIH resources and career pathways.

Response 1316

Perspectives on the postdoc roles and responsibilities

A postdoctoral position should enable an individual to continue with their training as a researcher and gain skills and experience to prepare them for their research career in academia. While functioning independently, a postdoc should design, organize and conduct specialized experiments using stablished scientific protocols, or in some cases design/standardize new protocols; summarize findings and publish results in research journals. In addition, a postdoc can have mentorship initiatives and have students or technicians under his/her tutelage.

Fundamental issues and challenges

There are several points that are currently affecting the quality of life of postdocs, starting with the salary. I am starting my fifth year and they are paying me the minimum according to the NIH. I believe, this is because I am an international postdoc and I have limitations in terms of grants to which I can apply. Because of this, my colleagues who can and have obtained grants have had their salaries increased, but since I cannot apply for any grant, I continue with the minimum. This not only affects my salary but also my CV and the possibility of me pursuing a career in academia. Also, as an international, I am limited to a certain number of years with a visa and therefore my contract is tied to it, generating even more anxiety/uncertainty than what is already generated by research in academia.

Existing NIH policies, programs, or resources

Open NIH grants to internationals, not just K99/R00, so that we have opportunities to "compete" with other postdocs. Due to the pandemic, most private grants were not available for a couple of years and by the time the resources were back on for internationals to apply, I was not eligible anymore for most grants.

Proven or promising external resources or approaches

No response

Response 1317

Perspectives on the postdoc roles and responsibilities

Training for faculty position: responsible for own research idea, plan, and execution, to be used as a jumping off point for future research as a professor on the tenure track.

Fundamental issues and challenges

Pay is terrible, no work life balance, expectation that you will have to move (dragging your partner or spouse along repeatedly) to wherever you have the opportunity. Prospect of doing multiple postdocs is terrifying. Lack of benefits (e.g m/paternal leave)

Existing NIH policies, programs, or resources

Unsure

Proven or promising external resources or approaches

Unsure

Response 1318

Perspectives on the postdoc roles and responsibilities

Opportunity to learn a transition fields, or gain a completely new skill, compared to the work done as a graduate student.

Fundamental issues and challenges

Tough to generalize, but lack of proper listings of available positions. Many graduate students can feel limited in which labs to pursue because they're only familiar with those that they follow on Twitter/post post-doc opportunities on twitter. Overall, poor pay is a contributing factor to poor retention and quality of life. Also, many recent graduates are ~30 years old and aren't particularly interested in moving across the country again for a couple years' position, and want to buy house/have family/settle down.

Existing NIH policies, programs, or resources

I think a proper job posting/website and salary increase would help make recruit more prospective postdocs.

Proven or promising external resources or approaches

No response

Response 1319

Perspectives on the postdoc roles and responsibilities

I view the postdoctoral position as a stepping stone in my career. It is an opportunity to grow my skills, gain experience and publications, practice research at the academic level, and better understand myself so that I can decide which job I would like to pursue long-term. I am not sure if I want to stay in academia and think that a post-doc position will help me decide, while also filling gaps in the knowledge gained over my PhD. Once in the position, I hope to be mentored while also producing original research.

Fundamental issues and challenges

As a prospective post-doc, I mostly worry about pay, finding the right mentor, and if the position will be worth it. I know I could find a higher-paying job with my degree and worry that a post-doc position will pay much less while also expecting much more (additional time in the lab, a move, or demanding mentors). For me and from what I hear from my peers, pay is the largest issue that discourages the pursuit of a post-doc position.

Existing NIH policies, programs, or resources

I don't know anything about NIH **policies, programs, or resources**for prospective or current post-docs, so I think the first step would be expanding exposure and clearly communicating what is available for people looking at this role.

Proven or promising external resources or approaches

Clarity of resources and higher pay, as described in previous questions.

Response 1320

Perspectives on the postdoc roles and responsibilities

The postdoc is traditionally a transition period to academic faculty positions, enabling new graduates to obtain skills not available in their thesis labs, and letting them develop their own projects as PI. However this transition has been up-ended since more than a decade ago by availability of more competitive positions in industry or other, such that as soon as a skilled postdoc ascends to the position, they are offered more lucrative jobs elsewhere.

Fundamental issues and challenges

Pay equity is the most fundamental issue barring retention of postdocs. Also the lack of assurance from their mentors or home institutions that they will move forward in their careers in the academic ladder, or institutional barriers such as lack of strong support from the institution demonstrated by availability of tenure-track positions, competitive salaries or retention even if the PI loses funding.

Existing NIH policies, programs, or resources

Increase NRSA levels for postdoc stipends. There should also be a concerted effort across institutes to teach postdocs the nuances of professional progression to a more stable academic position as future lab PI. However if even the established PIs feel insecure about their jobs due to lack of assurance of funding from ever lowering NIH paylines, the postdocs will see a bleak future for themselves. Essentially as new or early-stage investigators they can get great support in getting the first R grant, but then they are left on their own with low chances of getting funded afterwards unless they are at the very top percentile of all biomedical investigators. Postdocs see the lack of stability of this situation in their PIs and realize early on that they do not want to keep chasing multiple R01s in order to just get a semblance of (or never get) equitable salary, whether it's salary comparable to peers in well-funded institutions or in industry or other.

Proven or promising external resources or approaches

All of the above

Response 1321

Perspectives on the postdoc roles and responsibilities

Honing skillset as a scientist in the field that the PhD was done. Potentially serving as a mentor for graduate students and learning how to write grant proposals for potential role as a professional investigator.

Fundamental issues and challenges

Most postdocs positions are only open to people who have done mostly the same work as a PhD. This excludes students looking to develop a new skillset from being competitive and also may not be exciting for someone who did the same work as a PhD student. Also many postdocs are looking to become professors but since the demand for those positions is a lot more than the supply, the post doc then becomes a pseudo terminal role in academia for many. A PhD may see this in advance and choose to get a head start on their life and earning potential by not considering the postdoc in the first place and choosing to enter industry. Maybe if PIs advertise the development of new skills, for example someone who did a PhD purely on the bench looking to develop computational skills or other types of bench techniques from what they learned, maybe that could help with the issue. In the current setup, a scientist's entire future career trajectory is mostly decided by the barely informed decision they made as a first year choosing their lab. If they decide midway through their PhD that they might actually enjoy other types of science more, it's often too late for them and they become unqualified for a postdoc in that new field as well.

There should be the opportunity to reroute trajectory as a postdoc if needed. Also, if the postdoc is going to be a terminal academic position for the ones interested in staying in academia then it should probably be reflected in postdoc pay considering their industry alternatives.

Existing NIH policies, programs, or resources

I'm not too familiar with NIH capabilities. Maybe rewarding PIs with extra funding that actually value the "training" aspect of "postdoctoral training" and are not just looking for someone who has already mastered the techniques needed during their PhD.

Proven or promising external resources or approaches

I'm not sure.

Response 1322

Perspectives on the postdoc roles and responsibilities

Opportunity to receive additional training important for career development , publish major papers & prepare for next career step

Fundamental issues and challenges

recruitment has become a huge problem. Morale/motivation seems to be very low for pursuing academic careers. I also agree with the UC academic researchers and postdocs that their salaries should be higher, but now there is a huge gap between NIH postdoc salary level and UC levels, compounding the problem (faculty will now hire long term staff rather than postdocs—even if postdocs are available, which is rare—because the budget model isn't sustainable) . NIH needs to increase postdoc salaries , or the whole model is going to fail.

Existing NIH policies, programs, or resources

Increase the postdoc salary levels. it's that simple .

Proven or promising external resources or approaches

Increase the postdoc salary levels. i'l just keep repeating it.

Response 1323

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

Insufficient pay seems like the massive elephant in the room.

Existing NIH policies, programs, or resources

I don't know what policy or program this falls under, but pay people what they're worth?

Proven or promising external resources or approaches

No response

Response 1324

Perspectives on the postdoc roles and responsibilities

Contributes expertise/knowledge to the lab, able to provide a novel perspective or ideas to a research group. Someone who could spearhead their own project in the lab or perform experiments within another ongoing project in the lab (depending on group, expertise, etc.). Mentor for graduate/undergraduate students int he lab.

Fundamental issues and challenges

Salary is often quite low, especially because many are at the age where they might be looking to start a family. There is definitely a history of and ongoing toxic culture in many labs, so other job prospects

(especially ones that pay more) are often more appealing. Unless the trainee is interested in pursuing an academic career, I don't really know why a graduate student would choose a postdoc. If there was management training for PIs (the NIH Becoming a Resilient Scientists series was very helpful for me as a graduate trainee and an equivalent training for PIs might be useful) and more funding opportunities that rewarded the trainee rather than the PI, I think that would greatly increase retention.

Existing NIH policies, programs, or resources

Funding programs are great, would emphasize increased salary that goes directly to the trainee rather than takes financial burden from the PI. Application materials for NIH training grants/fellowships are confusing and not that informative.

Proven or promising external resources or approaches

Programs for senior graduate students to apply to that would provide postdoctoral funding (similar NSF GRFP for undergraduate students) that fund the trainee in addition to the PI (increased salary for the trainee but still provides some support for the PI). Mentoring networks with PI participants who have demonstrated a commitment to mentoring and opportunities for trainees to meet each other.

Response 1325

Perspectives on the postdoc roles and responsibilities

To me, the purpose of an academic postdoc is a temporary training position meant as a stepping stone to a tenure-track faculty position. Ideally, postdocs should be supported by their PIs to gain specific skills that they didn't receive during their PhD, develop their independent research program, and be guided through the academic job market (or any alternative job market the postdoc is interested in).

Fundamental issues and challenges

One of the most challenging aspects of supporting postdocs is the issue of security and stability. This has to be a delicate balance, because on the one hand, postdocs deserve financial stability, healthcare, and a good quality of life. On the other hand, postdoctoral positions are not meant to be permanent, which can sometimes inhibit some of these resources. The biggest challenges I have faced in my own postdoc is stability, which has hindered my research productivity greatly. For example, I have spent the majority of my time in my postdoc position applying for funding just to keep my position for the following year. This put me behind in getting research up and running, which then puts me behind on the job market and requires more grant writing. It is a vicious cycle. Now, as a more "senior" postdoc, I am ineligible for many grants and fellowships, which means I will either have to spend my remaining time as a postdoc writing multiple risky grants, or transition out of academia. My PhD is from a very competitive program and I have a number of publications from prestigious journals, so I really cannot imagine what this situation is like for postdocs at less competitive institutions.

Existing NIH policies, programs, or resources

The NIH could consider providing more training grants (like the K99, F32) and/or expanding the funding duration and eligibility years for these programs. More and more, postdoctoral positions are lasting longer than a year or two due to dwindling and highly-competitive academic job prospects. If PIs wish to be able to recruit postdocs, they will have to be able to offer higher salaries and increased job security so that postdocs have sufficient time to become competitive for the academic job market.

Proven or promising external resources or approaches

No response

Response 1326

Perspectives on the postdoc roles and responsibilities

I think for postdocs, especially in the sciences, it is unfair to keep thinking of them as temporary and to limit the term of them to only 6 years. While of course no postdoc wants to stay a postdoc forever, it is clear with the decrease in funding and open faculty positions that many are going to have to stay postdocs for longer than expected.

Fundamental issues and challenges

Personally I think the reason academic institutions are being about to obtain and retain postdocs and why academic postdocs do not have a great quality of life comes down to one simple thing. Pay. We do not get paid what we are worth. We are considered "still in training" while running experiments, labs and managing people. It is absolutely disrespectful to all that we have put in time wise, education wise and the knowledge we have when a tech with no undergrad degree is making $6 less an hour than us. Its basically as slap in the face. In industry you are paid for your knowledge and skill and in academia you simply are not. In industry you are also compensated in some way or form for overtime and treated as an employee. Most postdocs receive none of this treatment in academia including the given the same benefits as normal employees (who they normally work more hours than). Simply the government needs to step in and make a mandate that postdocs be MANDATED to be FULL EMPLOYEES of their university. NOT SECOND CLASS. Otherwise academia will continue to lose good scientists to other avenues every year.

Existing NIH policies, programs, or resources

If we are still considered "in training" and are not going to be paid to our full potential I don't think it is fair for postdocs to be required to pay their student loans back. We are just starting to make money after YEARS of struggling to get by. If a person chooses to take a lower paying job to stay in academia they should not have to pay back student loans. Unless those years count towards a 10 year public service forgiveness program at a public institution. But they should get that choice.

Proven or promising external resources or approaches

[redacted for anonymity] is one of the few universities that treat their postdocs as FULL EMPLOYEES with complete benefits. Parental leave, sick leave, holiday leave, personal leave, health, dental, vision, etc. Their model is great. With a PAY INCREASE [redacted for anonymity] would be the best university in the US to postdoc at in academia.

Response 1327

Perspectives on the postdoc roles and responsibilities

I view it as an opportunity to fully develop into an independent researcher that will take on a leadership role (PI in industry or academia). As such, it means having the opportunity to develop your own research program and ideas, and to learn how to manage a lab and other mentorship activities such as teaching, training PhD students etc. Although this could be considered training, I see it as a full-time job for someone who is extremely qualified, having earned their PhD. Thus, they should be compensated as an extremely well trained researcher.

Fundamental issues and challenges

The first challenge is the salary. You do not make much more than you made as a graduate student, despite being much better trained and having a doctoral degree. Industry jobs pay so much more with an arguably lighter workload, better benefits, and better work-life balance.

Second, many "successful" PIs are not well trained to be mentors (and may not care about mentorship at all), and they go on to send many postdocs on to faculty positions based purely on their name. These postdocs continue the cycle of not being good mentors, so many postdocs positions in successful labs suffer from poor mentorship and will perpetuate the excess of poor leaders in academia.

Third, the difficulty of obtaining a faculty position. Many of the criteria and requirements to obtaining a faculty position are unclear, and it's not guaranteed that as a postdoc you will be guided on how to best navigate the process.

Existing NIH policies, programs, or resources

More accessible funding, and raising the pay scale for postdocs. Specifically funding that requires postdocs to make an active effort to obtain leadership skills, rather than focus solely on research

Proven or promising external resources or approaches

No response

Response 1328

Perspectives on the postdoc roles and responsibilities

I'm a NIH-funded postdoctoral fellow and chose to this training year(s) to be a transition time between graduate school and an academic faculty position (fingers crossed). I felt that I needed more mentorship and training within academia in order to become a successful externally funded research scientist. During my clinical psychology PhD program, I focused much of my efforts on my clinical training and was not part of a large externally funded lab. My research experiences in graduate school were varied (I took research opportunities when available with multiple investigators both at my home institution and remotely). Thus, my "research program" was not cohesive, I did not have grant writing experience, and I did not understand the culture of an academic medical institution. I chose my postdoc based on strong and high quality mentorship (even above the perfect research "fit") because I needed guidance with this transition. Before my postdoc, I felt extremely ill-equipped for academia and would likely have chosen a full-time clinical position if postdoc wasn't an option.

Fundamental issues and challenges

Postdoctoral trainees are underpaid, which is challenging after being in debt following graduate school. As part of the clinical psychology PhD, we have the clinical internship year as our final year of graduate school. During this year (the year before my postdoc), I worked 60 hours/week (doing research after my clinical days—most nights and weekends) and did not make a living wage. After rent, I barely had enough money to buy my groceries and was unable to take out federal student loans to supplement my income (we are not allowed to during this year). As a single woman with no partner to supplement my income, I felt privileged to have my parents to help me pay for things extremely meaningful to my mental health (e.g., gym membership, travel money to visit friends for social support). Six years of graduate school, providing clinical services throughout a pandemic, having a massive amount of student loans, and never making a living wage, have culminated into feeling "burnt out". It is stressful to now be writing a K23 because I will be unable to remain at my academic medical center without this funding. As an example of financial stress as a postdoc—during my first few months I had research accepted at a national conference. My NIH-funded postdoc paid up front for the flight and registration, but I was expected to pay for my hotel and food out of pocket and then be reimbursed. My bank account went to $0 by the end of the trip (my credit card has been maxed out since internship year). Waiting for reimbursement for several weeks, I was eating stale food out of my pantry, which was depressing and dehumanizing to be doing with a PhD. I also regretted submitting to this conference.

Existing NIH policies, programs, or resources

Higher pay and security of two (or even three) year contracts would help people feel more stable and have a less stressful time applying for externally funded positions as they transition to faculty. If I had a partner or children, I would not have taken this postdoc because of the instability. It's a one year contract that can be "renewed" possibly for a second year. It seems relatively unlikely that it won't be renewed, yet still not guaranteed. My academic medical institution is purely "soft money", so I will need to secure a K23 or move again (which is expensive). Also, as an NIH-funded postdoc I pay the maximum amount of taxes because I am technically an "independent contractor" at my institution. Taxes are not taken out of my payroll and I was given no education or heads up about this. Figuring out how to pay/how much to pay for my taxes has been just another mental burden. I also pay more taxes than my friends who have postdocs with PI's. So, I somehow feel punished for securing a NIH-funded postdoc. Although the difference might seem insignificant to some, I cannot emphasize the impact of several hundred dollars to my bank account.

Proven or promising external resources or approaches

In my opinion, to retain more diverse researchers into postdoctoral positions, the simple answer is higher pay and better job stability. Having a position in academia that relies on external grant funding is unstable in nature, but I think it is most a threat to mental health and quality of life when this instability follows so soon to being a graduate student. The only reason I am staying in this postdoctoral position is because I am receiving excellent mentorship and I am privileged to handle the instability and financial stress (no children, financial help from parents). However, I am still considering all my options (industry included) because the stress of paying off student loans (I applied for the NIH LRP—waiting to hear), paying off my credit card, and applying for external funding is not sustainable.

Response 1329

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

Salary is way too low

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1330

Perspectives on the postdoc roles and responsibilities

I have always been told that a postdoctoral fellowship is meant to fill in gaps from your graduate school. It is there to add skills or experience in a field that may have been lacking in your grad work that will help you further your career as a scientist. It also allows opportunity for mentorship, both under a new PI and to mentor underlings.

Fundamental issues and challenges

1) The pay is a joke. The current entry level pay for a postdoc put out by the NIH is $54,835. There is a KFC I drive by on my way to work that is offering that much for managers for what I imagine is a lot less work. Prospective post docs have spent the last 5 years scraping by on grad student stipends that barely cover living expenses going through emotional and professional turmoil. The salary that is being offered in most post-doctoral positions does not reflect the level of training and specialized skill set that we spent years developing. Not all institutes will match the NIH payscale either and are offering less. I will say outright, the only reason I chose to post-doc is that my partner is financially stable enough that money is not an issue. To add to the pay issue, the level of benefits offered to postdocs may not be matching what industry is offering. Some people may put off having kids until their postdoc and if there is not parental leave that is a non-starter. The quality of health insurance and annual leave may also impact the choice to go to industry instead of academia.
2) Toxic Environment. There is no such thing as work-life balance in academia. We pretend there is, but there isn't. All the editorials are griping about how we don't want to work anymore. We do, just not in the same toxic environment that all the PIs who are clearly still scarred from that toxic environment and projecting it onto the future generations. Shouldn't we want things better for people because we suffered, not want it bad for everyone because that's the way it was for us??

I have more thoughts, but I am out of words

Existing NIH policies, programs, or resources

The fact that I had no idea the resources existed says a lot. I am vaguely aware of some of the grants, but perhaps an officer at every institute or per region that could explain what these are to people who aren't in the know could be helpful.

The policies website is unreadable/unapproachable. So there is that.

Proven or promising external resources or approaches

My institute offered a moving stipend. My institute realized that moving is expensive and difficult and offered me a tax free stipend to help my move. I could see how a move could be prohibitory for a lot of people.

Offering more money. Industry is offering 2-3x the NIH starting post doc salary. After 5 years of scrimping and starving, I could see why people would take that over pursuing a post doc.

Eliminating the toxic PIs.

Response 1331

Perspectives on the postdoc roles and responsibilities

My view of a postdoc was to achieve scientific independence, learn grant writing, attend conferences, publish, lead a project, obtain a job, etc. What happened during my postdoc was that I basically was a research assistant the entire time.

Fundamental issues and challenges

1) Low Salary. My salary does not cover the cost of living (medications, groceries, etc.) in a safe apartment in a major US city.
2) Loneliness. I had to move across the country due to the limited number of postdoc opportunities that matched my area of scientific interest. I had no friends or family to support me with this transition.
3) Lack of Support to Reach Scientific Independence. PIs should be evaluated based on the number of K99/R00 applications they submit vs. what is funded to encourage PIs to promote scientific independence for their postdocs.
4) Publication. Postdoc positions are short. The idea of "intellectual" contribution should be very clear to PIs vs. 10 years of physical presence in a lab to be included on a publication.
5) support to find a tenure-track job.
6) travel reimbursement. I was not given adequate funds to travel to conferences, which held me back from disseminating my science.
7) Lack of mentorship training. The mentee should hold a key to their own success not their mentor. We should encourage mentors to make a change (i.e., mentorship courses, etc.).
8) Lack of Voice. Postdocs have no one to express their frustrations/concerns with. The NIH should create a safe place for postdocs to gather and discuss strategies to overcome barriers.
9) Quick response to change. The NIH needs to do something now. If this postdoc dilemma does not end soon, current postdocs may discourage future students from pursuing a postdoc and the dilemma will only get worse.

Ultimately, if the NIH makes a change, I am confident universities will follow—and if enforced on grant applications—universities will have no choice.

Existing NIH policies, programs, or resources

Increase the salary and remove restrictions with giving bonuses to individuals who work incredibly hard. Provide moving stipends that count as a reimbursement and not taxable income that go up to $5,000 (or $10,000 if possible). Provide yearly travel funds that go up to $5,000. Provide additional mentor support networks and workshops. Require PIs to give postdocs authorship & include postdoc positions on R01 applications. Require PIs with postdocs on R01s (or equivalent grants) to take mentorship courses. Require R01 (or equivalence) PIs to report postdoc development plans and quarterly follow up reports to the NIH if a postdoc is on an NIH grant (other than the typical T32).

Proven or promising external resources or approaches

NIH Resilient Scientist Training Course was great.

The postdoc education office was a great resource at my university.

Response 1332

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

Lack of adequate salary and benefits are by far the biggest challenges inhibiting recruitment, retention, and quality of life. As a postdoc, I make significantly less than I could if I left academia for full time clinical work or industry. My earning potential has already taken a huge hit from many years in graduate school.

This is only exacerbated by the inflated expectations for admissions into graduate school today—I needed to obtain additional experience prior to being accepted to a doctoral program, and so completed a two-year masters program, followed by five years in my doctoral program, a ridiculously underpaid clinical internship year where I had to take on debt to live, and now postdoc. In my institution, I am not given any benefits as a postdoc other than extremely limited student health insurance that is paid out of my institutional allowance on a T32, also limiting my ability to conduct research and receive additional training. If I am lucky enough to only complete one year of postdoc before transitioning to faculty, that adds up to essentially a lost decade—a decade accumulating debt rather than savings, zero retirement benefits, minimal health benefits, etc.

Existing NIH policies, programs, or resources

Salary and benefits MUST be increased, and health coverage should not be taken from institutional allowances. Postdocs also need retirement benefits, paid family leave, larger childcare subsidies, and reproductive health benefits like egg freezing.

Proven or promising external resources or approaches

Salary and benefits must be comparable to industry.

Create postdoctoral fellowship opportunities that are bridge or transition programs to faculty slots. Institutions need to create more faculty lines if they want to keep attracting postdocs.

Response 1333

Perspectives on the postdoc roles and responsibilities

The primary role of the academic postdoc is to prepare graduate students to become principal investigators. Side roles would be to give recent PhD graduates additional experience in their chosen field or to allow them time to decide on a career path.

Fundamental issues and challenges

Graduate school delays achievement of a permanent position, and postdoctoral fellowships further delay this during a time in life where people would like to settle down. Many postdocs have young families and would like a secure job with benefits, good pay, and in a long-term location. For postdocs who do not have young families, there's the concern of delayed retirement contributions (no 401k, etc.; low wages don't allow for IRA contributions). The culture around science is also disheartening (delaying stability, permanence, and family life for the pursuit of research; bias and discrimination against women and minorities, especially those who took a break for pregnancy, mental health reasons, etc.)

Existing NIH policies, programs, or resources

At my agency, it's common for a postdoc to stay 4-8 years (up to the limit), but at universities, the postdoc can be as short as 1-2 years. Delaying a permanent position for 1-2 years is much more manageable than for 8 years. Although a postdoc can stay here shorter than 4 years, it's not the common refrain we hear—longer is the norm. Additionally, postdocs basically get 'kicked out' of my agency after 8 years, even if they want to try to stay in a permanent position. There is no good process for a postdoc to transition to a staff scientist, or even a contractor. This is even worse for visiting postdoctoral fellows who are up against visa requirements and clocks.

My agency has made good progress on postdoc leave (vacation time and parental leave), but I feel there needs to be more support for trainees with small children and young families. Paid childcare on campus? Also, housing is a huge issue—it's so expensive in this area and the postdoc stipends are lacking. A young family would NEED two working parents if one were a postdoc to pay both rent and childcare. Lastly, there are no ways for postdocs to get retirement matching from their employers since they are not considered "employees."

Proven or promising external resources or approaches

benefits like free gym memberships, paid childcare, other wellness subsidies; expanded telework and remote work options

Response 1334

Perspectives on the postdoc roles and responsibilities

A semiprofessional position in which the researcher is highly trained and adds expertise to the laboratory, but financial independence and mentoring skills are still building.

Fundamental issues and challenges

Financial stability, especially within major cities with high cost-of-living. It is standard for universities/departments/labs to compensate postdocs the minimum salary based on the NIH recommendations—please raise these and consider language that takes into account the financial landscape of major cities. Similarly, employee benefits such as retirement matching or parental leave should be mandatory. Postdocs are spending 5+ years, usually throughout their 30s when many would like to start families. Without these basic securities and support, it is a difficult choice to stay in academic research knowing better benefits are available elsewhere.

Existing NIH policies, programs, or resources

Please include language protecting F32 awardees from a non-employee title/status change. Accepting my F32 resulted in a loss of W2, certain benefits including pretax FSA/HSAs, and taxation of my health benefits, all equating to ~$3000 in lost benefits and costs to me. This is financially harmful, and the lack of tax form has made it difficult to apply for a home loan.

Proven or promising external resources or approaches

No response

Response 1335

Perspectives on the postdoc roles and responsibilities

I absolutely love my postdoc position great projects great mentorship. Flexible timings help me as a new mom too. Without the flexible timings I would have quit.

Fundamental issues and challenges

I'm a postdoc in [redacted for anonymity], salary is a huge issue. 85K is necessary to survive with a family in a city like [redacted for anonymity],rents and daycare are unbelievably crazy here. For Indian postdocs H1-B visa processing delays are a huge issue too, option to renew it in the US, will prevent postdocs from getting stuck at a US Consulate in India. If I got a competitive offer from Switzerland and US, as an Indian postdoc I would pick Switzerland coz I can visit my family once a year without stress. Ability to visit family makes one more productive and NIH must pay heed to this, especially postdocs from India that are plagued by this.

Existing NIH policies, programs, or resources

More training programs to reskill in industry in demand skills. Programs must be offered remotely so more postdocs can participate. Example Seq data processing. Less than 5 percent of Biology Postdocs can be PIs, reskilling options for the rest is definitely not a fools pursuit.

Proven or promising external resources or approaches

1. Ability to renew H1-B academic and J-1 visas in the US for postdocs. NIH must approach USCIS regarding this
2. Increase in salary for [redacted for anonymity] and other metropolitan area postdocs, factoring in rent and daycare.
3. Reskilling courses along with funds to reskill postdocs in industry relevant skill sets.

Response 1336

Perspectives on the postdoc roles and responsibilities

In the best sense, post-doctoral scholars are highly trained scientists who are in the prime of their scientific career. They are masters of methods and close to the data but also have experience writing

manuscripts and grants. Together this can mean a very productive period in their career. Post-docs should be encouraged to publish high-impact work and then move on to a non-trainee position quickly, if possible.

Fundamental issues and challenges

For many people the post-doctoral training years coincide with a time where big life changes are happening including getting married, having kids, being more interested in one's financial future, buying a home, and having older parents in need of financial or medical assistance. For women especially, there is a sink or swim mentality when it comes to "making it work" being a full-time post-doc and raising babies and small children. This time, when children are under 5, is intense and unlike any other era of childrearing. For many, it is untenable to remain in academia as a trainee as kids require round the clock childcare (from a parent or paid provider) and costs quickly begin to rival the post-doctoral scholar income. Post-docs need real childcare subsidies and help with buying homes. Otherwise they will leave for jobs that pay better and that allow them to achieve balance between their personal and professional lives. If that means fewer post-doc positions because they are more expensive, then so be it. Post-doc positions should be well-paid (or at least provide benefits needed to traverse this time in life) and competitive to get. Graduate students should not default to post-doctoral positions only to realize later that the financial model makes it impossible for them to grow personally.

Existing NIH policies, programs, or resources

Childcare cost benefits that actually cover the cost of childcare when kids are under 5 years old.

Proven or promising external resources or approaches

No response

Response 1337

Perspectives on the postdoc roles and responsibilities

The postdoctoral position, as far as I can tell, is a way for academic universities and PIs to have a steady source of underpaid labor under the guise of "training". In industry, people who have a PhD and drive science forward are called "scientists" and are paid appropriately for their contributions. In academia, by calling postdocs "trainees", institutions and PIs can underpay them. I basically view it as a period of making no money with no promise of any payoff, where the only theoretical payoff (of a faculty position) depends on publishing in high impact factor journals and is no guarantee. For the majority of people (those who do not end up getting a faculty position), it is inferior in every possible way to industry. Furthermore, for a large fraction of labs, a high number of postdoctoral positions are held by PhDs from other countries. I think this is because academic institutions have essentially identified that by holding the ability of people to stay in America over their head, they can underpay and overwork PhDs from other countries to form the backbone of American biomedical research. Suffice it to say, I think this is a bad and exploitative system and would be less bad and exploitative if we offered international PhDs permanent residency for their contributions as well as paid them a living wage.

Fundamental issues and challenges

The number one issue by far is the lack of fair pay for postdoctoral scientists. I can make at least 2.5 times as much money in industry doing the exact same type of experiments, with better hours. That is the exact reason why this year I will be leaving my postdoctoral position for industry, in order to make enough money to live.

Existing NIH policies, programs, or resources

Increase the NIH pay scale for postdocs. The NIH pay scale for postdocs, which essentially sets the salary at most institutions in America, is abysmally low. The pay scale should be equivalent to industry. Why should an academic postdoc make less money for doing essentially the same job as industry scientists?

Proven or promising external resources or approaches

The NIH should learn from the one and only current place that is actually able to recruit top level PhD level scientists: industry. The reason industry can recruit postdocs is not complicated at all: it is that they pay postdocs fairly. It has absolutely nothing to do with any of the things mentioned above (e.g. more recruitment efforts, more training, working environment, mentoring, or job satisfaction). The last thing I

as a postdoc would want is more responsibilities or required session that take away from time to do science. I don't want more required mentoring or training responsibilities. I want to be paid at the level of a scientist in industry.

Response 1338

Perspectives on the postdoc roles and responsibilities

My understanding is that the postdoc position exists to allow trainees to expand upon their technical research skillset, grant application skills, resume/CV/publications list, and professional network. It also seems like a makeshift, stopgap measure to provide graduate students a kind of purgatory to work in until they succeed in getting a faculty position or are forced to apply to jobs outside of academia.

Fundamental issues and challenges

As a MD-PhD student who plans to pursue both clinical practice and basic science research, I worry about the potential length or utility of a postdoc position after at least 7-8 years of graduate training and 4 years of residency.

Existing NIH policies, programs, or resources

Response 1339

Perspectives on the postdoc roles and responsibilities

The postdoctoral position has become a necessary sacrifice that an early career researcher has to make if they hope to have a small chance at attaining a research intensive faculty position. After graduate students have become experts in their field they often are asked to switch fields of study, as well as move to new institutions, often located across the country or world from their current location just to prove they can be successful in another environment. While the postdoctoral position is considered a "training" position, in my experience most postdocs serve as the most technically skilled and productive members of their labs, functioning as the main workforce for academic research labs while also providing training to researchers earlier in their careers. Often postdocs also become de facto lab managers as their PIs tend to spend less and less time in the actual lab environment as their own careers progress. Additionally it is often expected that postdocs can and will apply for and secure funding for their own salary, as well as conceptualize, plan and execute their own original research in order to carve out their own niche in their fields. None of this is inherently bad, in fact much of it was the reason that a postdoc seemed like the perfect position for me after I finished my graduate work. However, it has become an issue as compensation is simply not commensurate with the plethora of duties required of a postdoc today. Stated plainly, in many institutions and academic research labs the postdoc has become essential to the progress of many scientific fields and yet the compensation for that role has become a chance at a faculty position in a highly competitive job market where they will slowly no longer use their much of their technical expertise.

Fundamental issues and challenges

The most obvious fundamental issue is poor compensation. Salaries have not kept up with inflation rates and dramatic increases to cost of living in general. A postdoc is often asked to create an original research plan, obtain funding for their own salary to work on that research plan, and then to complete that research in a timely fashion, and publish it in a "high impact" journals. After they've successfully done so they can consider applying for the more properly compensated faculty positions, but they must often do so at new institutions again across the country or world. The academic research community is telling graduate students that they will be trained to do this work, and in fact must prove they can do so before being allowed to graduate. But then, upon graduating, they are asking those same students to prove it all over again and do so while being underpaid when compared to similar level jobs in industry settings. I've long been assured that once you obtain the highly sought after faculty position, the last decade you've spent working towards that goal now feels worth it. But at the same time I've watched early career PIs

struggle to obtain funding and ultimately lose their faculty positions because they are suddenly seen as a much riskier lab to fund compared to their more established former mentors, now colleagues. How can we expect to effectively recruit and retain the best postdoctoral "trainees" if we've watched them undergo a literal decade of training in the system and yet don't fairly compensate them for that research and then also don't trust that their training was actually adequate when it comes to actually awarding them grant dollars to continue their work?

Existing NIH policies, programs, or resources

I strongly believe that any postdoc being paid by NIH dollars, either "directly" through F, T, or K grants, or more indirectly through R grants or other mechanisms should have their salaries directly determined by the NIH. And that compensation should undergo a significant increase. Additionally the NIH needs to raise the funds granted by R mechanisms as many PIs will say that they would be willing to pay postdocs more, and yet say they are unable to because despite inflation the still get the same amount of money each time they successfully renew their R01. Finally the NIH should mandate that all institutions must pay their postdocs in the same manor. At my institution the university treats all postdocs who receive F or T funding as independent contractors and therefore is not required to give us W2s or 1099s, resulting in much more complicated tax filings. This also makes it much more difficult to verify your own income when applying for loans such as for housing, making it (for me personally) impossible to invest in the housing market as lender didn't understand what the postdoc position was and why I was being paid in the way I was. My institution also doesn't allow postdocs to apply for the maximum salary offered by the NIH for K awards. I know this is not true for all institutions, but the NIH certainly has the power to tell all institutions receiving these funds how they must use them, in order to fix this issue. Instead, as it stands now, the postdoc position at my current institution seems to be the one the university cares the least about, and the only way I foresee that changing is by the NIH forcing them to change it through their own policy implementation. Good Luck

Proven or promising external resources or approaches

The only "external resource or approach" I know of that relates to this is the fact that most industry postdoctoral positions pay higher salaries and have actual roles within those same companies that they are providing real training for these postdocs to fill. If higher paying research scientist roles (a role between a PI and postdoc existed), then the postdoc could potentially truly be a training position that could lead to either a faculty position or a similar research scientist role. Unfortunately the current NIH funding system doesn't offer much incentive to hire well paid highly qualified research scientists, when PIs know they can get the same work done for less by hiring a new postdoc as a "trainee". Perhaps the NIH should considering providing funding mechanisms that would better support such roles.

Response 1340

Perspectives on the postdoc roles and responsibilities

The postdoctoral position is an opportunity to grow, develop, and hone scientific skills needed to better lead and address scientific questions. This position is intended to take the pre-doctoral training to the next level by providing independence, mentorship opportunities, and the space to investigate sceintific questions creatively.

Fundamental issues and challenges

I think the pay is a big challenge in recruiting post-docs. It is much easier and more enticing to enter into other scientific careers where one can be paid much more money, receive benefits, and set themselves up for a secure future. Another issue inhibiting recruitment is the length of a postdoctoral position. Over the past few years, postdoctoral training has gotten longer and longer. Another five to six years (which is very common recently) is not appealing to doctoral students. I think having shorter postdoctoral positions would result in more students pursuing a postdoctoral position. Another problem that I see with postdocs is the lack of incorporation. When in academia, there are plentiful resources for students and professors have their niche, but this same supportive environment is lacking for postdocs. It looks like a very lonely and isolating position that most people take into account when they are deciding to pursue academia or not.

Existing NIH policies, programs, or resources

I am unsure about the current policies, programs, or resources, so I cannot speak to what specifically could be changed.

Proven or promising external resources or approaches

Altering the working environment to be more like a position in the scientific field (i.e. better pay, supportive environment, etc.) would increase interest in postdoctoral positions.

Response 1341

Perspectives on the postdoc roles and responsibilities

In general, I view the academic postdoc as the only realistic transition into an academic faculty position. You gain more research experience and publications and become more independent.

Fundamental issues and challenges

Postdoctoral positions are highly underpaid relative to industry jobs. Even more discouraging is that a postdoc salary is comparable to the average starting salary of a college grad with only a Bachelor's. It simply makes no financial sense, so only people who are already financially well-off and deeply invested in science will consider a postdoctoral position. Academic culture can also be quite toxic, and the work-life balance is poor.

Existing NIH policies, programs, or resources

Imposter syndrome is real--I think open and honest discussions about it are always helpful. NIH workshops on the topic are helpful and should possibly be mandatory for those supported by NIH funding.

Proven or promising external resources or approaches

Improve stipends, offer financial planning resources (retirement planning), skill workshops for postdocs hoping to gain expertise outside of their lab's expertise, better communication of grant opportunities (for those whose mentors are not necessarily describing different grant types and benefits)

Response 1342

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

No response

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1343

Perspectives on the postdoc roles and responsibilities

I view my postdoctoral position as a training period. I am using it to gain new skills (technical and intellectual) so that I can be well-equipped to ask unique research questions as an independent academic researcher. To achieve this goal, I went to a lab where I could learn new skills by applying them to my PI's research goals. I also have the benefit of being in a well-established lab. This allows me to develop my own research aims. The net effect of this training + exploratory phase means that my postdoc will probably be a long one.

Fundamental issues and challenges

Academic research has its perks: flexibility in schedules, freedom in research. But people need more concrete benefits in order to flourish. I think that basic benefits are especially lacking for postdocs and is reflected in the exodus of people from academia into industry and other positions.

Postdocs tend to be at ages where they are starting families, moving all over the country (and probably away from extended family and childcare support), and at an ideal age to make investments into retirement accounts. None of the needs associated with these pivotal life stages are systematically managed, uniformly distributed, or institutionally protected for postdocs.

Existing NIH policies, programs, or resources

Childcare funds: regardless of individual funding, all trainee parents should have pay adjusted for children and childcare expenses

Administrative supplements: regardless of career stage or funding, all trainee and early career researchers should be allowed to apply for administrative supplements

Proven or promising external resources or approaches

Trainee infrastructure: Consider giving more advanced postdocs (+2yrs experience) funding support for undergraduate trainees or technicians. This would grow the scientific workforce, shift less technically advanced tasks from postdocs while still advancing the mentor/PI's research, and build in managing experience for postdocs as future PIs.

Basic benefits for postdocs: this seems silly to need to say, but many postdocs are not unionized and do not have basic benefits like paid family/medical leave or retirement benefits.

Bonuses are used by many fields, but not typically given for academic research. Academic research can be very thankless, so it is important to acknowledge people for things like method development, publications, and grant submissions (funded or not).

Response 1344

Perspectives on the postdoc roles and responsibilities

I view the academic postdoc as a method of gaining the skills needed to become an independent scientist or to prepare for a career that requires a postdoctoral training element (even a lot of teaching focused positions now require a postdoc for example due to increased competition for positions). This is also an opportunity to expand your scientific knowledge and technical skills beyond that of your graduate education. While many would argue that this is only training for gaining an academic PI position, the truth is that there are not enough positions open for all postdocs to become academic PIs (nor are all postdocs cut out to be academic PIs for various reasons), and therefore I believe that this training period also needs to make sure that postdocs are prepared for other positions outside academia as well. Many skills, including technical and leadership skills, are relevant to many scientific positions and can be developed during the postdoc with the right training environment.

Fundamental issues and challenges

I think that two of the biggest issues are pay and expected working hours. When postdocs look at industry colleagues, they see that their compensation is not close to what their colleagues with similar education/skills make in industry positions. This is also reflected in the lack of retirement benefits accrued as a postdoc. Additionally, work-life balance can be challenging as a postdoc when competition for faculty positions is really high, making industry work-life balance also look more attractive (more 9-5 hours expected). Lastly, postdocs often feel like an afterthought at many academic research institutions, with the available resources much more focused on student/faculty productivity, training, and satisfaction (for example—career development offices, administrative contacts, research highlights, etc). This seems to be slowly getting better, but we aren't there yet.

Existing NIH policies, programs, or resources

Pay/compensation could be better for postdocs (though I realize that grant money awarded would likely need to be higher as well so that PIs can afford postdocs from grants). Resources that help postdocs with career development are also necessary as not all postdocs will ultimately end up in academia and if they

do, they need education on the non-bench related aspects of being a PI. Without the right mentor, it can be difficult to learn the world of grants, managing personnel, committee responsibilities, and finances that come with running a lab, etc. While the goal is to keep people in academia, we also need to have positions available for these people in academia without keeping people as postdocs forever or as poorly paid non-tenure track faculty who live on one year renewable contracts that don't ensure any kind of job security. Postdocs that do not stay in academia also need to be able to have the skills and knowledge to find an industry positions if they do not find a PI position. It may be comforting to people to have the safety net of knowing that they feel prepared to make that transition if applications for PI positions do not yield desired results.

Proven or promising external resources or approaches

No response

Response 1345

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

Life science/biology perspective: Pay is dramatically lagging compared to any other professional opportunities I could pursue after getting my PhD. No pay negotiating capacity either. Most people are entering their PhD with already a few years of research, and PhDs take 5.5-7 years (and are in themselves already a significant opportunity cost for life sciences where I've estimated just doing the PhD cost me 150-200k in potential lost wages). Doing a post-doc would probably equate to another 200-300k of lost wages.

Existing NIH policies, programs, or resources

Response 1346

Perspectives on the postdoc roles and responsibilities

-Perceived role = a subject-matter expert whose job is to expand scientific exploration per the scope defined by their PI/their PI's grants

-Perceived purpose = generally career advancement, as an intermediate stage between graduate school and lectureship/professorship; also a skill-development period for learning a particular tool/method/approach

Fundamental issues and challenges

No response

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1347

Perspectives on the postdoc roles and responsibilities

A postdoc is fundamentally a training position, so while it involves training in and performance of technical skills that benefit my lab, it is also a time that I can develop my career resources. A postdoc is a good time to learn industry-facing skills that can both drive my project and benefit my long-term career

development. Considering a postdoc is lower paid with few benefits compared to industry, the pay-cut comes with the understanding that I can spend time on career development, especially since the likelihood of getting an academic position is so poor compared to the options in industry.

Fundamental issues and challenges

Having children during the postdoc is difficult because there's no support and no benefits. If my husband didn't leave academia for industry we wouldn't have been able to afford me working because of daycare costs. He gets paid parental leave and I get unpaid FMLA and, honestly, I'm not sure that anyone in academia would actually protect me from getting fired for getting pregnant. Because I want a family, I don't want to try to be a PI, because the careers don't seem very compatible, compared to the benefits available in industry.

Existing NIH policies, programs, or resources

I honestly don't know what benefits are available? Perhaps it would be helpful to better communicate what the existing policies, programs, and resources are?

Proven or promising external resources or approaches

Having actual parental benefits for postdocs would be a huge step forward.

Response 1348

Perspectives on the postdoc roles and responsibilities

A postdoc is a stepping stone for an academic career or a stopgap for a recent graduate as they finish the last parts of their thesis work before going on to industry. If you do not aim to become a PI there is little reason to pursue a postdoc, outside of needing immediate employment.

Fundamental issues and challenges

Compensation. Postdocs are severely underpaid just based on their contributions to society alone (ie the benefit research provides to the greater community). Once you factor in the time it takes to complete doctoral work in order to apply to be a postdoc and the hours a postdoc works the compensation is even less appealing. Academia as seemingly decided that someone who has proven they have the intellectual acumen to be considered at the top of a scientific field (arguably the most difficult field to understand and excel in) is valued at the same level as a recent business bachelors degree recipient, which is insulting. If the compensation improved then even the long hours and poor treatment by some superiors would be ameliorated.

Existing NIH policies, programs, or resources

Outside of mandating a substantial pay increase there is little policy can do to improve the postdoc conditions. Policies will always be ignored and avoided by those they are meant to reign in and reporting those that break policy can have negative repercussions for the whistleblower.

Proven or promising external resources or approaches

N/A I have no knowledge of any such resources

Response 1350

Perspectives on the postdoc roles and responsibilities

I did my postdoc training at [redacted for anonymity]. I was lucky to be in a well funded lab, and I had my freedom to design the experiments and perform the experiments without worry about the cost. However, my advisor, like many professors, did not help me to achieve my next career goal by guiding and giving me supports. Although I had several good publications at the end of postdoc, I did not have a seed grant to find a position in a university. My postdoc salary was even less than the one I had as a lab scientist after I graduated from college with a BS. The postdoc training is long and fruitless to me. I did not go on to do the research that I was interested. I know some postdoc stuck a this position for years and finally just become a tech in an academic lab. Many people went to graduate school with a dream to contribute to science, and just to realize it is a nightmare to be a scientist. Some of them became a professor but once they run out the grant, they are kicked out the universities.

Fundamental issues and challenges

The advisors do not care about postdoc or their graduate students. Postdocs and graduate students are often treated as cheap labors for the professors. Not enough NIH funding or any funding to help postdoc advance in their career. Basic scientific research is not respected. Only research with practical values like treating human diseases, advance human life will get funded. I think most of people choose science not for the money but lack of career path, making the years of training as a waste. It is also hard for life science scientists to transition into non-research related career.

Existing NIH policies, programs, or resources

Currently, universities will only hire people with grants, and if the assistant professor does not have NIH funding within certain time period, he/she will be out. Getting funded often time depending the ability of person to networking, and I think many scientists are introvert and they lack the skills of social networking. To improve the ecosystem, USA needs changes at NIH and universities. Universities used to be places for thinking, debating and investigating, but now universities are running like for-profit business. Professors, graduate students and postdocs are just the money making machines for the universities.

Proven or promising external resources or approaches

There is no cure for the next 20 years since the whole system is corrupted.

Response 1351

Perspectives on the postdoc roles and responsibilities

A postdoc should be a training position to develop the skills needed to run your own research lab. It should be spent developing a project/topic that can be used to start their own research group as well as developing skills in grant writing, manuscript preparation and mentoring.

Fundamental issues and challenges

Two fundamental issues exist: low pay and the length of postdoctoral training. The pay is too low, especially in high cost of living areas, and therefore it is hard to compete with biotech where beginning salaries are 2x higher than postdoctoral salaries. Postdocs are often stuck for several years (often more than 5 years) before they are able to be competitive for faculty positions.

Existing NIH policies, programs, or resources

Increase the minimum salary for postdocs, or adjust for cost of living to make it more affordable to complete a postdoctoral position.

Proven or promising external resources or approaches

No response

Response 1352

Perspectives on the postdoc roles and responsibilities

Training position as stepping stone to true career goals

Fundamental issues and challenges

Paid like trainees but expected to produce expert work with minimal guidance/mentorship; pressure to publish in clearly broken system; lack of job opportunities after postdoc; pyramid scheme nature of academia

Existing NIH policies, programs, or resources

Formulaic writing style required for scientific publishing / grantwriting; unnecessary hoops to jump through / incredibly opaque multi-step process regarding submitting NIH grants

Proven or promising external resources or approaches

Higher pay (comparable to tech where other people with similar skillsets work)

Response 1353

Perspectives on the postdoc roles and responsibilities

I see a postdoc as a way to mature as a scientist. A PhD teaches you how to identify problems and carry out a project, and a postdoc is for repeating that process several times over a shorter period of time. In doing so, one is ideally able to carve out their own scientific niche wherein their skill set, knowledge, and current research direction is unique.

Fundamental issues and challenges

It is an entirely unstructured position. There is no mechanism to motivate PIs to hire postdocs with the intent of managing their postdocs well. It is also a poorly paying position. After a PhD, many trainees can get a job in industry immediately, sometimes doing high quality, academic-like research within a company. The lack of reliable stipend and training makes a postdoc a riskier position to pursue.

Existing NIH policies, programs, or resources

The standardized stipend rate should be increased in general, and should be revised to account for increased cost of living at different institutions.

Proven or promising external resources or approaches

No response

Response 1354

Perspectives on the postdoc roles and responsibilities

A short-term training for the faculty position.

Fundamental issues and challenges

Lack of clarity on the purpose of training. I don’t think someone going into industry, consulting or entering a non-academic workforce need postdoctoral training.

Lack of awareness that postdocs are most likely in their 30s and 40s and are sandwiched between raising their families and taking care of parents on a meager stipend.

The insistent that postdoc should treat their position as though it’s their life or a do-or-die affair. It’s not. It’s a job and should have clear boundaries.

Existing NIH policies, programs, or resources

OITE. This has been a great resource for career development, exploration, job search etc.

Expand the K grant requirement beyond the current 4 years eligibility

Proven or promising external resources or approaches

Increased salary support. A lot of institutions will not willingly increase postdoc salaries citing NIH standards, so NIH needs to provide substantial increases yearly or utilize a locality pay adjustment. $50,000 in Idaho is very different from $50,000 in Boston or San Fran.

Creating policies that help postdocs from a predatory mentor. Policies that protect the postdoc or reward the postdoc for excessive overtime in lab.

Response 1355

Perspectives on the postdoc roles and responsibilities

[redacted] pay for [redacted] hours and no guaranteed upward mobility, even if you have the ideal academic pedigree, things might not work out. Not enough money to save for life events or for the expensive activities and education of children—I didn't pay a dime for my Ivy League education or associated expenses because my dad was in finance. Would I be able to do the same for my kids while supporting a spouse like my dad did? And live in a nice upper middle class area with access to excellent schools to let me work at the NIH during summers in HS and college and then do the postbac IRTA after graduating while living at home to save money? I'm at a very established MSTP right now and have no interest in pursuing a postdoc at the expense of my clinical years/salary. I would rather be connected to industry and rake in money if that opportunity was available.

Fundamental issues and challenges

No long-term financial or career stability

Existing NIH policies, programs, or resources

More $$$$$$$

Proven or promising external resources or approaches

Literally look at industry

Response 1356

Perspectives on the postdoc roles and responsibilities

It seems a postdoc is required if one wants to be a research focused college professor. Because of this unofficial requirement, I believe individuals get taken advantage of. Postdocs are cheap, overworked scientists. Making $45-50k annually is terrible pay, especially if being asked to work over 40 hours a week. I think many people in science are realizing this in today's world and don't want to get taken advantage of anymore. Additionally, becoming a grant chasing faculty member with no guarantee of tenure (or available faculty positions) at a research intense university doesn't offer work-life balance and I think covid reminded people that life is more important than work. We work to live, not live to work.

Fundamental issues and challenges

See above. Unions, benefits, better pay (by a lot), and appreciation are warranted. Not a mindset that postdocs are cheap scientists that can be milked for all that they are worth.

Existing NIH policies, programs, or resources

see above

Proven or promising external resources or approaches

see above

Response 1357

Perspectives on the postdoc roles and responsibilities

The KL2 program was invaluable to providing me time, mentorship, resources, and education to prepare for an independent research career.

Fundamental issues and challenges

The impact of virtual or hybrid education and conferences reduced the quality of my experience, although it improved safety and convenience.

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

Some of the best research opportunities are in the highest cost of living cities and the NIH minimum salaries do nothing to reflect this. Private academic institutes rarely pay above this minimum and if they do, it's not nearly enough or competitive with industry standards. It is increasingly difficult to support yourself, let alone any dependents with the extremely low compensation provided for arguably the most important/productive pool of scientists in the country.

Existing NIH policies, programs, or resources

Wages need to increase otherwise all the talent will leave for industry. This is actively happening, we see it everyday. The problem is compensation. Not only do postdocs take extreme salary cuts relative to industry, but they also miss out on extremely important years for retirement investment with employer matched 401ks etc.

Proven or promising external resources or approaches

Fundamental issues and challenges

One hundred times over—pay. My first year as a postdoc in 2018 paid 54k in Washington DC. I was "lucky" to be still young, meaning no mortgage, no kids, and thankfully minimal health expenses. Absolutely cannot imagine surviving on that salary in areas as expensive as DC with a family and/or a chronic disease that required regular care. Don't underestimate pay. People have to live and whereas we don't do science for the money necessarily, it's what the landlord and bank and utility companies ask for at the end of the month. I can't buy groceries by showing my PhD diploma and the noble scientific work I'm doing. Indeed, a postdoc is still a training program, however, with significant less oversight + we are engaged in important research. Those two at the very least should justify being paid more than a PwC auditing intern recently out of undergrad (I wish I was making this up, but I'm not. They get paid more). I am happy I pursued a postdoc and found it to be a valuable experience, but I struggled. These experiences shouldn't only be appealing or feasible for folks who benefit from a well-paid spouse or parents who can support them.

Existing NIH policies, programs, or resources

Any payment related policies. Start there and I think you will see changes. Don't do it, and the recruitment pool will get thinner and thinner.

Proven or promising external resources or approaches

No response

Response 1360

Perspectives on the postdoc roles and responsibilities

It's a glorified placeholder to continue underpaying productive scientists as they stagnate amidst attempting to secure the fewer and fewer tenure-track faculty positions they are trained for and expected to pursue.

Fundamental issues and challenges

1. Competetive Pay. The graduate school process is 6-8 years long and underpaid, making productively saving for the future nearly impossible. Upon finally earning one's Ph.D., usually between the ages of 26-36, new doctorates are offered a $40k-$60k post-doc position—a salary that is competitive with laboratory technicians whose job does not require a doctorate. After postponing or struggling to plan for the future and/or start a family it is no wonder that more and more PhDs choose to leave the standard post-doc=to=academia route in favor of more financially sound and rewarding careers outside of academia.
2. Job Opportunities. A growing number of studies have shown the limited availability of tenure-track positions for Ph.D. graduates, particularly within the life sciences. Reports have estimated as few as 1 in 4 to 1 in 8 Ph.D. graduates will attain a tenure-track academic position, the touted golden standard outcome of Ph.D. training. With so few opportunities, this makes the idea of sitting in the underpaid queue of post-docdom even less enticing given there is no promise this incubation time will lead to a tenured faculty position. Many see and are concerned by the vast over-production of PhD graduates to the limited number of tenured faculty postitions we are told to aspire to. This is in stark contrast to our medical doctorate counterparts who boast greater than 80% placement into residencies which typically transition directly into an outlined career.
3. Academic Detattchment. Lastly, many new PhD trainees are interested in using their talents to more directly engage with the society they serve. Partly, in response to the lack of academic positions resulting in more PhD graduates sharing their stories of finding fullfilling jobs outside of academia, and partly in response to witnessing the importance of scientists' role amongst the public during the recent pandemic.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

One place to start from (although admittedly not a full solution or a silver bullet) might be to start with requiring NIH-funded academic institutions to track and make transparent career outcomes of their graduates and post-docs. This type of transparent system could both help recruit more post-docs who see certain institutions as more successful in helping their trainees as more attractive and help elaborate the picture of if more post-docs are needed or if a new research faculty pipeline should be considered to meet this need.

Another idea to consider is expanding financial and family benefits/accommodations for post-docs. Presenting the position of post-doc as an academically valued position for an accomplished Ph.D. graduate to pursue rather than as a temporary, unmeaningful placeholder position as the name "post-doctorate" implies may attract more graduates to these positions. Two ways of making this position seem more valuable and meaningful, are to pay it competitively (both across industry salaries and comparatively within technician and primary investigator salaries) and/or provide enticing supplemental job benefits as mentioned previously; or to restructure Ph.D. training programs to include post-docs as pipelines directly into specified positions, similar to medical residencies.

The problem is not that Ph.D. graduates do not want to do post-docs. The problem is that post-docs are becoming increasingly obsolete as their main perceived function is to funnel researchers toward ever-non-existent faculty positions. Since a minority of Ph.D. graduates go on to tenured faculty positions, those who take the post-doc route and don't make it, end up leaving academia for non-academic positions which never required a post-doc to begin with. This feedback loop filters into current graduate students who pivot away from wasting their time with a post-doc, toward the non-academic jobs most graduates are getting anyway. The post-doc problem is a functionality and narrative problem.

Response 1361

Perspectives on the postdoc roles and responsibilities

I view postdoc as continued student training with no degree. In some cases, for successful postdocs who are granted the independence to develop lead their own projects and manage a small team within a lab, it can help pave the path forward towards becoming a professor. In other cases, it can provide additional skill training for industry. In many cases, it is simply another student who reports to the PI and works on their projects, with some more senior authority in a group hierarchy than an entering graduate student.

Fundamental issues and challenges

I see a postdoc training as significantly worse than a graduate student training.

1. there is no degree awarded at the end
2. the stipend is not significantly better—and may be worse if you consider loss of student benefits (such as health insurance)
3. job security is lower and other student protections are lost
4. many student benefits are lost (ex: freedom to take and teach classes at will, student support networks, etc)
5. in a well positioned/funded lab, a senior graduate student could have the same intellectual freedom as a postdoc. Such a graduate student may prefer to stay in that lab, rather than join another lab where those freedoms may not be guaranteed.
6. Conversely to (5), a graduate student in a not-well positioned or funded lab may not have the resume to get a position in a very well-positioned postdoc lab, and as such may end up in a more subserviant/workerbee situation to the PI in a prospective postdoc, leaving them with the same decision metric as in (5).

(1)-(6), in my view the incentives for a postdoctoral training are aligned when a graduate student is required to move on but is not ready for a faculty position, but *desires* an academic faculty position, and thus must continue academic training as a postdoc. With less faculty jobs and more postdocs on the market, as the academic job market further intensifies in competition, there is even less incentive.

Existing NIH policies, programs, or resources

NIH grant support for taking / teaching classes while a postdoc? Resources for this?

Response 1363

Perspectives on the postdoc roles and responsibilities
I see the academic postdoc as an opportunity to publish dissertation research and to apply for tenure track positions within academia. I also see it as an opportunity to join another lab, see how another lab approaches science, and an opportunity to get more or more intense training in a domain or methodology that you were unable to get during your doctorate.

Fundamental issues and challenges
LOW PAY!!

Postdocs literally have doctorates but are not getting paid like they have doctorates. This still boggles my mind. Additionally, not only are they not getting paid at the level of their degree (as evidenced by the industry jobs which pay so so much more), they are also often not paid enough to live in the city in which they live.

Aside from the fundamental issue of low pay, I also see issues of having to move for only 2-3 years, especially if the postdoc has a family to move with.

I want nothing more to be a tenure track professor, but I can’t ask my partner, who makes significantly more money than me, to move to another state (forcing him to get a new job) so I can do a very low paying postdoc for a few years (before we then move again for a tenure track job). Unless I can find a remote postdoc, this relocation issue will probably force me out of academia. I am fortunate enough to have a partner who makes a lot of money so I don’t have to worry too much about the pay, but if I did not have him, I would be panicking about the low pay.

Existing NIH policies, programs, or resources
Increase the postdoc salary cap by a lot, set up something to provide or help with child care, encourage remote postdoc opportunities, cover relocation expenses if the postdoc is really forced to move.

Proven or promising external resources or approaches
Please take a good close look at academic twitter. It is constantly abuzz about this specific issue. There are a lot of good ideas about this on there from researchers smarter and more creative than me.

Response 1364

Perspectives on the postdoc roles and responsibilities
Doing research, managing experiments and becoming an expert in your field while also preparing for the next stage of your career (usually academic/tenure track professorships in which you keep the postdoc topic as your future research)

Fundamental issues and challenges
Low funding and salary; people spend 5+ years earning PhDs and becoming experts in their field and should be paid as such. Lack of inclusive environments and support for postdocs from underrepresented communities and the uphill battle they face in academia.

Existing NIH policies, programs, or resources
Further increase in the minimum postdoc salary at the ver least

Proven or promising external resources or approaches
No response

Response 1365

Perspectives on the postdoc roles and responsibilities

I view my position as my last chance to focus 100% in science done with my bare hands.

While PhD research involves much training and faculty position involves much teaching, bureaucracy and working on getting funding.

I see this time as directed to scientific discovery.

Fundamental issues and challenges

I think the main issue causing the brain drain is pay.

While here in CA we saw significant improvement after the last strike, still today there are lot of biomedical research carried outside academia that offer pay that is 2-3 times higher—some companies are doing interesting work. So it seems that most postdoc must be extremely privileged, non-american, or very reluctant about industry research in order to stick with basic science.

Most leading R1 campuses are located in the most expensive areas in the US.

Existing NIH policies, programs, or resources

Allow J1 visa holders same access to NSF and NIH grants.

Increase pay substantially

Make NIH funding more daring. I think that many postdocs the projects NIH selects too conservative. We are young and seek risk, otherwise we would switch to a well paying industry job. It should be easier to win grants on pilot projects. Also the median age of grant winners gone much higher—we need more funding for ECR that want do break things than older folks who might be very experienced in grant writing.

Proven or promising external resources or approaches

Allow in passport entry visa to be extended from within the US—currently after DS2019 was extended but entry visa expired the postdoc and his family cannot leave the US and go back without going through the US embassy in the country origin. This interfere with international travel, e,g for conferences while in postdoc.

Response 1366

Perspectives on the postdoc roles and responsibilities

Academic workhorses—while training to move on to the next position, post-docs are the lifeblood of whatever institution they are working for. In the current academic environment of "publish or perish," the grand majority of those publications come from post-docs. This means that the grand majority of grants are written on the back of research and publications from post-docs.

Fundamental issues and challenges

Pay. Post-doc pay is embarrassingly low when compared to alternate career trajectories with the same, or even lesser, credentials. Why should someone go into an institution as a post-doc when their pay is capped at below $60k a year? For the level of expertise and training a post-doc brings to their work, this number is a slap in the face, especially when industry jobs are able to pay more than twice that at an entry level, with benefits AND a more healthy work-life balance. Post-docs are often expected to work hours that are well above and beyond the 40-hour work week, and due to the nature of being salaried, any time above and beyond 40-hours is work done for free, on top of the already ridiculously under-valued work they already did for 40-hours. I personally have been to multiple scientific conferences, including AAI, where focus groups have been held, and this very question has come up multiple times—"how do we get more post-docs and keep them?" The answer that is repeated over and over again, from post-docs, lab managers, and PIs, is more pay. The people at every level doing the actual academic work understand this and have been championing this cause for a long time. It's hard to recruit post-docs when fresh PhD graduates see that they could, instead, enter into a job that appropriately compensates them for their work. In the current economic climate, $60k a year is far from a sensible amount to pay post-docs. Sure,

$60k a year may sound impressive to a PhD student who is also criminally underpaid, but any positive feelings about that number fade instantly when industry offers, at a baseline, almost quadruple that. Pay is the number one issue preventing post-doc recruitment and retention.

Existing NIH policies, programs, or resources

Pay post-docs more.

Proven or promising external resources or approaches

Pay post-docs more.

Response 1367

Perspectives on the postdoc roles and responsibilities

To me, there are two sides to postdoctoral positions. The positive side is that it is an opportunity to hone my skills with further training and mentorship as well as protected time to apply for a K level grant. However, it also feels like a necessary sacrifice for those of us who want to eventually have an independent research program within academia. This sacrifice is mainly financial and personal. Postdoctoral positions pay far less than industry roles and faculty positions, additionally postdoctoral positions do not offer the same job security as other roles. I will be entering this role knowing that I will need to go through an additional application and interview process to obtain a secure position. This lack of adequate pay and job security in conjunction with a lack of paid parental leave result in great personal sacrifice especially in the case of female scientists who are have committed most of their childbearing years to their training.

Fundamental issues and challenges

As described above, the fundamental issue in my review is a lack of adequate financial support which reflects the level of training and earning potential in other positions that postdocs have. Postdocs sacrifice their quality of life and delay majorly important life events including home buying, starting a family, and investing for retirement because of the lack of pay and security in these positions. Again, this personal sacrifice amplified in those trainees who come from disadvantaged backgrounds and who are female.

Existing NIH policies, programs, or resources

The NIH's loan repayment program is a great program but should be expanded. If every NIH funded (intra—and extramural) trainee was automatically accepting into this program that would greatly improve the well being of trainees. Furthermore expansion of paid maternal and paternal leave as well as funding for childcare is needed.

Proven or promising external resources or approaches

The negative impact of stress on creativity and productivity are well known. The private sector recognizes this and companies often offer flexible work schedules, paid leave, childcare, IVF and other family benefits, fitness and wellness benefits, etc. to support employees as whole beings. The NIH needs to see postdoctoral trainees whole beings with personal, social, family, and financial needs rather than as just scientists. Doing so would greatly impact recruitment, training, and job satisfaction.

Response 1368

Perspectives on the postdoc roles and responsibilities

Performing independent research. Supervising undergraduate/graduate projects. Collaborating with other groups. Starting to apply for research grants, with or without PI.

Fundamental issues and challenges

Poor salary.

Visa issues.

Lack of control by NIH/institutions to enforce NIH policies.

Existing NIH policies, programs, or resources

Poor salary. Often departments/PIs do not follow NIH policies and when they do they may only do it partially (i.e. just adapting the minimum salary without considering year of experience).

Visa issues, especially J1 holders: impossibility to apply for small grants, especially indipendently from the PI; insurance requirement for the visa are old and not updated with the current insurance policies (e.g. deductibles); lack of reimbursement for visa-related expenses; pressure on the government to streamline the visa application/renewal process for academics.

Lack of control by NIH/institutions to enforce NIH policies.

Proven or promising external resources or approaches

Look at the EU fellowships from the Horizon program. A model similar to that would create a more balanced, vibrant and diverse research environment.

Response 1369

Perspectives on the postdoc roles and responsibilities

Postdoctoral positions are a chance to expand and hone skillsets aimed at advancing your career to a desired level. You are responsible for project conception and management, much like a PI, but within a structured environment that offers mentorship as needed.

Fundamental issues and challenges

Salaries need to be competitive with industrial positions. That’s it.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1370

Perspectives on the postdoc roles and responsibilities

The point of a post doc should be to train individuals to manage a lab, write independent grants, and develop a research plan that the individual will continue for their career. It seems over the last several decades that post docs have become more like second PhDs, where researchers spend a lot more time at the bench and developing a project and gaining further scientific training,

Fundamental issues and challenges

Pay! In [redacted for anonymity] many lab technicians and managers make more than post docs. It’s really discouraging to have worked so many years and then get paid under 60k. Further, many institutions provide affordable housing for graduate students but not postdocs so almost all of the increased earnings from PhD to post doc go toward finding suitable housing. It’s understandable that a post doc is still a training position but many industry post docs pay much higher (think 70-80k) which would be a noticeable quality of life improvement over the PhD beyond just paying for in subsidized rent.

Existing NIH policies, programs, or resources

Increased number of transition awards with better pay for post doc years

Incentives for reducing postdoc training time

Proven or promising external resources or approaches

No response

Response 1371

Perspectives on the postdoc roles and responsibilities

I am on my second postdoc and both have been very different experiences. Ultimately, the postdoctoral position to me means a time to gain further training needed to run your own research program. In my first postdoc this was a time filled by mostly technical learning, writing and presenting work. In my second postdoc I've had a chance to also teach, mentor, and take on leadership roles. Altogether, I feel like these experiences and roles are important for preparing a postdoc for the next steps but not everyone is able to find environments where they can have access to all of these training opportunities.

Fundamental issues and challenges

There has been strong progress in salary levels and time to advance from postdoc positions in the past 5-10 years, however, many of the trainees that came slightly before these programs, such as myself, are still struggling with the old system opportunities since I am too far along in my career to qualify for transitional fellowships (6th + year postdoc). Offering special career development support to aspiring scientists who were left behind would be helpful as they have many years of valuable training and experience to offer. Additionally, despite the recent progress, we still need increases to salaries and benefits due to inflation and the skyrocketing cost of living in big cities.

Existing NIH policies, programs, or resources

- More programs for advanced postdoc candidates to transition would be helpful. As a 6th year postdoc, I am not eligible for many training or transitional grants so I recently applied to a new diversity R01 program. I was thrilled to see that a component of the application focused on diversity efforts which I have a strong record of. Unfortunately, the application went to a traditional study section for review and I fear that the panelists, while experts in their scientific field, did not find value and importance for the DEI work that was a big part of the application. I understand that ultimately, I will be competing for grants based on my science and that needs to be accepted and supported by the community, but if NIH truly wants to place value on DEI work, then proposals should be reviewed by scientists who fully understand and value this work.
- There is a strong need for additional family friendly/support policies.
- Subsidized housing in cities with high cost of living.
- External career development training and opportunities (coming from NIH instead of individual institution).

More funding support for PIs that take trainees. Even though trainees often find additional funding sources for their salary, costs of experiments are high and in order for labs to adequately support trainees and provide excellent training environments and career development opportunities, additional funds are needed.

Proven or promising external resources or approaches

No response

Response 1372

Perspectives on the postdoc roles and responsibilities

With greater experience a PostDoc provides more of the innovative thinking or brainstorming. They often come in with other skills and are well-prepared to learn new skills and bring them to the lab. Educate and lead by example up and coming graduate students.

Fundamental issues and challenges

Bottom line. It is a lot of work to spend hours, days, and nights working and thinking about science. There are a lot of pitfalls before there are successes, and the pay is not enough for the 16-hour days I have seen some postdocs commit themselves to in an effort to complete science in a more timely manner.

Existing NIH policies, programs, or resources

Funding. We spend more on tools than the people working the magic with said tools.

Proven or promising external resources or approaches

Work environment could also improve, especially atmospheres that advocate for a work-life balance.

Response 1373

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

Postdocs need much higher wages, to be paid a wage and not a stipend so that postdocs can contribute to their retirement, postdocs should also get their retirement contributions matched by the institution (aka benefits that a non-academic job would provide).

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

MORE MONEY

Response 1374

Perspectives on the postdoc roles and responsibilities

A postdoctoral position is the dream job. In theory, we have the freedom and are supported to pursue research topics we are passionate about. In theory we get the resources to immerse ourselves in the science like no other time in our career.

Fundamental issues and challenges

In practice it's a nightmare. In institutions like Princeton where there isn't a problem recruiting postdocs, PIs can get away with being abusive, not providing any kind of meaningful mentoring, and transferring the pressures of their jobs to the weakest link, the postdocs. We work ridiculous hours and weekends, in projects that might not give publications that will advance our careers. It's publish or perish, but even perishing takes everything from us. We don't have a life apart from work, we have to postpone or forgo plans to have families, because even if we had the time we wouldn't have the money. We sacrifice everything because we are passionate about what we do. Many of us live paycheck to paycheck, hoping there won't be any unexpected expenses. Having children is not affordable, but being single is not affordable either. Renting an apartment as a single person takes more than half the salary. We avoid going to the doctor for regular checkups because we can't afford it as, at least for international postdocs, this is not included in the medical plan. It's a matter of time some issue won't be detected on time and people die. Nobody cares about our conditions but we feel we have to be grateful for having this amazing opportunity to work in something we love and make a difference. If any of the problems affects our motivation or productivity we risk losing our job. It's supposed to be a training position, but all the guidance and mentorship goes to the graduate students. In the case of international postdocs all these issues add to the isolation and lack of social support. We know we need to work as efficient machines or will be discarded, but even a successful postdoc doesn't provide any job stability.

Existing NIH policies, programs, or resources

We need more programs open for international postdocs.

Proven or promising external resources or approaches

No response

Response 1375

Perspectives on the postdoc roles and responsibilities

I see the postdoctoral appointment as a 2-3 year position where a recently graduated PhD scientist can learn new techniques in a different or related field to their PhD research that will either equip them for a

successful industry career, or position them to create a niche as an academic tenure-track researcher. If the postdoc wants to pursue an academic career, this time is critical for them to investigate and publish on a new area that they can take with them for their independent research program.

Fundamental issues and challenges

The biggest issues inhibiting recruitment, retention, and quality of life is the low pay and sacrificed earning potential. It is insulting to be paid this little after having >10 years experience in an academic research setting. The low pay coupled with the moving goalposts of attaining a tenure track faculty position seem dismal. Additionally, the money allocated from different NIH institutes towards transitional awards (i.e. K99, K22, etc.) is low, making attaining these awards incredibly difficult and favors institutes and investigators with a wealth of resources (i.e. Stanford, Ivy leagues, MIT, HHMI investigators, etc.). Together, these challenges make budding researchers not want to spend their time on an academic postdoc if they can go right into industry and start their careers. It makes doing a postdoc a luxury afforded only to individuals who are independently wealthy and can afford 2-6 years of missing out on a much higher earning potential offered in industry.

Existing NIH policies, programs, or resources

Increase baseline salaries for postdocs starting at $75,000. Increase the overall budget for each R01 to allow for this increase in salary. Increase the allocated funding towards postdoc training and career development awards such as the F32, K99, K22, etc. Increase the budget for MOSAIC awards to increase the number of researchers from historically marginalized groups going into tenure track faculty positions. Write policies that can ensure that new mothers receive ample paid maternity leave and that fathers get paternity leave. Increase additional funds for cost of living expenses such as daycare stipends and inflation adjustments.

Proven or promising external resources or approaches

Pay us more money. This will fix pretty much all of these problems. Even if the salary is not as competitive as industry (e.g. postdoc making $75k a year vs. industry postdoc/entry level scientist making $100k per year), individuals who want to pursue academic careers but cannot afford to live in urban areas with the current stipend will be more likely to seek out a postdoc. In my own opinion, if I didn't have to worry about making ends meet, I would be much happier and feel much more satisfied with my working environment and job satisfaction. I am a postdoc and currently am living paycheck to paycheck and seeking out "side hustles" in order to save up for "regular life things" including a car, a wedding, and a future down payment on a house.

Response 1376

Perspectives on the postdoc roles and responsibilities

The ideal academic postdoc would be a bridge position to train aspiring researchers to become faculty at a research institution. However, the current role seems to be that the academic postdoc is the workhorse of the lab—expected to produce data for PIs with little attention paid to development of their own career. Prior to entering graduate school I had viewed a postdoc as a logical next career step, however, my impression of it has changed substantially to the point that I now view it as a last resort. I view the lack of compensation, long hours and poor training as something to be avoided and there are very few labs in which I would consider a position.

Fundamental issues and challenges

Academic postdoc pay has never been reflective of the highly educated, trained personnel in the role. Hours worked seem to be based on work expected rather than a rational work-life balance, regardless of whether that work load is reasonable. The emphasis on training seems to be dependent on the PI of the lab rather a standard set by the NIH, which seems absurd given that the limits on pay are tied to NIH policy. Despite postdocs being of the age where they must choose whether to start a family, there is typically little or no consideration given to time off or work/life balance. I've encountered many postdocs who have said they have not had a vacation in more than a year and some who had not take one in 5 or more. Moreover, there is an incentive for PIs to exploit these issues in their favor—the less they spend and the more they work their postdocs the more successful the PI is.

Existing NIH policies, programs, or resources

While the NIH is not the perpetrator of these problems, it is the poorly designed rules established for grants that drive this behavior. F-32s are one mechanism that the NIH could expand to ensure appropriate training standards, but I think it likely that this approach would be insufficient. Any grant that includes a postdoc position should include a training plan that is reviewed by the grant review panel, and every progress report should have a private portion sent to each postdoc asking their input on whether the training is going to plan. By necessity this data could be kept private and an aggregate used as a modifier to future grant scores given to the PI, providing them an incentive to train the personnel they committed to.

Proven or promising external resources or approaches

The failure of the current system reflects that the standards set by the NIH do have a driving effect on the quality of life, and therefore retention of postdoctoral researchers. It is critical that improvements to pay, mentoring, training and working environment be standardized as a condition of NIH award money. Only with funding in jeopardy will we achieve the kind of systematic change that will help retain, train and grow our postdoctoral workforce.

Response 1377

Perspectives on the postdoc roles and responsibilities

It is a training process for graduate students or post-graduate students to gain more knowledge or skills for the future career development. It’s also a great opportunity for phd students who would like to do a transition to a new research area. The main roles of academic postdocs would be conducting research aiming to solve scientific questions and contribute to science development.

Fundamental issues and challenges

The low payment barely covers the living cost. Only a small percentage of postdocs would end up in academia.

Existing NIH policies, programs, or resources

Adjust the salary arrangement for postdocs.

Proven or promising external resources or approaches

No response

Response 1378

Perspectives on the postdoc roles and responsibilities

The postdoc role ideally serves two main functions,

1. to further the scientific and professional development of an individual, and
2. to supply research labs with competent staff. Within a lab, a postdoc should be the lead investigator and driver of several projects capable of producing high quality publications.

These projects should support the needs of the PI, but there should also be room for projects that the postdoc is interested in as long as there are somewhat relevant to the overall focus of the lab. A postdoc should mentor other lab members, ideally creating a team. A postdoc should be the primary author of papers and grants, and should present at scientific meetings. Postdocs should also get involved with outreach.

Fundamental issues and challenges

1) Pay is not competitive. It will cost me roughly $500,000.00 in lost potential earnings to complete a postdoc. I chose this because I love what I do, but the other 5 members of my PhD cohort are all in industry now for this reason. The pay doesn't need to exactly match industry, but it needs to be better than half.
2) Geographical/life stability. 2-5 more years of living somewhere temporary. I moved across the country to start my postdoc, and every time I had a chance to make friends, find a dentist, when I though about buying a house or a car, I never did because of the constant refrain in my head that this is temporary. This is for both geographical and financial reasons. "I'll save more money when I am making a real salary" for example.
3) Burnout/Work Life Balance
4) Publication rates. Publications are the currency we are building as postdocs. Slow publication rates make postdoc fellowships drag on and on, and after a while people give up and get a job in industry. This is due to inattentive or reluctant PIs and the general length of the publishing process.

Response 1379

Perspectives on the postdoc roles and responsibilities

A postdoc is a person in charge on its own project (scientific, budget—finding a grant and/or fellowship if possible, people—internship or technicians) under the supervision of a PI. They also have to develop out of the lab skills such as networking, scientific communication, lab origination.

Fundamental issues and challenges

Low pay

Very limited PTO

Variable benefits

No mandatory paid parental leave

Low or non existent dependents care

Existing NIH policies, programs, or resources

Open NIH funding to internationals individuals.

Proven or promising external resources or approaches

Postdoctoral unions in multiple university have met and talked with a lot of postdoc with different backgrounds, they are the one who knows best postdocs challenges and have worked on how to change that.

Response 1380

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

SALARY SALARY SALARY.

I do not mind working as many hours a week as we scientists tend to do. But the fact of the matter is that this is unsustainable when stipends are so low. Although I would love to do a postdoc after graduating, the

bottom line of finances means that I am 100% focused on transitioning to industry instead of remaining in academia for a postdoc position like I would prefer.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1381

Perspectives on the postdoc roles and responsibilities

A postdoc is a career stage after the PhD is finished in which a scholar can finish publishing their dissertation papers, develop new areas of expertise, and begin building their unique research program. Some of their time is directed towards PI initiated projects, but there should be time for the postdoc to develop their own ideas and apply for their own external funding.

Fundamental issues and challenges

Pay and benefits is the biggest challenge for postdoc recruitment and retention. This is especially an issue in places where the cost of living is high (San Francisco, Los Angeles, New York, etc). The NIH minimums are not sufficient for postdocs, and cost of living adjustments are necessary to fix this issue. Earning $57,000/year in [redacted for anonymity] is just not the same as earning that amount in San Francisco or New York City. Many postdocs have families and the current system requires having a partner who subsidizes the family budget, which is an issue for equity.

Existing NIH policies, programs, or resources

Please implement a cost of living adjustment for postdoc pay.

Proven or promising external resources or approaches

No response

Response 1382

Perspectives on the postdoc roles and responsibilities

Fundamental issues and challenges

1) Compensation: the base salary cannot cover the cost of living and the annual increase fails to match inflation.
2) Visa struggles: visa renewal often take weeks if not longer. For international trainees, the long visa processing time means a choice between pausing work for weeks or not visiting family until the completion of postdoctoral training.
3) Poorly-structured training: postdoctoral trainees often fill many roles at once: researchers, mentors, lab managers, etc. Without a clearly-defined training plan, a postdoctoral trainee relies on the good nature of a PI for mentorship and support.

Existing NIH policies, programs, or resources

Two ideas to ease the financial stress:

1) Implement a cost-of-living-adjusted salary; trainees in expensive places need higher salaries.
2) Permit postdoctoral trainees to receive compensation on the unused vacation days.

Proven or promising external resources or approaches

No response

Response 1383

Perspectives on the postdoc roles and responsibilities

Postdoc is an academic job with the nature of transitioning to academia or industry.

Fundamental issues and challenges

1) For international postdocs without a green card, there are very limited funding resources from NIH and other agencies.
2) Current salary for the postdoc in academia is much lower than the similar position in industry.
3) Postdocs commonly experience substantial pressure and poor work-life balance. For some university, they do not provide retirement benefit (401k) to postdocs.

Existing NIH policies, programs, or resources

Increase funding opportunities for international postdocs who work in the US without green card. Also substantially improve current standards for postdoc salary.

Proven or promising external resources or approaches

No response

Response 1384

Perspectives on the postdoc roles and responsibilities

If I were to do an academic postdoc, I would consider my chief responsibility to be to carry one or more scientific projects to completion (insofar as anything can ever be completed) over a relatively small period of time (2-3 years). During that time I would help train and mentor newer trainees as any senior lab member is obligated to, and I would focus on gaining skills and knowledge about the more arcane academic arts (getting funding, managing technicians and students, wrangling facilities, etc etc). I genuinely do not think it makes sense to consider it a traineeship. It is a job.

Fundamental issues and challenges

I am 28 years old and looking at graduating within the next 6-9 months. My parents are aging and beginning to encounter health difficulties that they may not be able to pay for on their own. I have my own health problems and need good health insurance. The concept of being in my 30s and earning $60k, being unable to help my parents, still having to scrape and never go on vacation and and cook dinner even if I'm exhausted and getting home late, and having to work so hard just to keep my career afloat, is an absolute nonstarter. I have an academic postdoc offer from a PI I get along with, whose work I think is important and interesting, and whose lab I think would benefit from the techniques I learned in grad school. But I'm not going to take him up on that when I can earn six figures with great benefits doing work that more directly benefits people. It just does not make economic sense.

Frankly, postdocs need to be valued and not paid a pittance. They are people in the middle of their lives, at a time when many decide to start families and when parents begin to need support. They're highly trained workers who could earn more doing essentially anything else. With the pay scale how it is, you need to be independently wealthy or marry rich to make it work.

Existing NIH policies, programs, or resources

Pay $100k, mandate plat level health insurance coverage and pension plans. Do a better job communicating what on earth it is postdocs are being trained to do, because as is it seems like calling postdocs trainees is mostly a scheme to justify low wages.

Proven or promising external resources or approaches

No response

Response 1385

Perspectives on the postdoc roles and responsibilities

Required step between graduate school and getting a biomedical science professor job. It is supposed to be a chance to learn new skills and expand on the analytical skills learned in grad school to become independent in ability to conceive of ideas, implement solutions, train/mentor students, write papers/grants.

Fundamental issues and challenges

The postdoc system in the US as it exists now is toxic and full of abuse. It is built to be survived by those that the system already values. It is inherently biased. Your success as a postdoc is tied to your boss so directly that if they do not believe in you, mentor you, train you. you will not become a PI. You will not even be able to apply to become a PI. If your boss is BAD AT THEIR JOB, you will not be trained, mentored or supported. You will be left on your own to survive and maybe succeed. Now do that while being URM or historically excluded.

This also depends on you being HIRED in the first place. Most US Postdoc positions are not advertised. They are applied for privately, through PRIVATE email conversations. No records. At public institutions or paid for by public (NIH) funding. No accountability at all for who is getting interviews or jobs. Imagine how this shapes the URM postdoc population.

Ok, retention. As I mentioned there is a gauntlet to survive if you do not have an excellent mentor. Most mentors are not excellent. Most mentors are bad. How are you going to retain people that are overworked, undervalued, existing in toxic environments who have already survived the less toxic but still NOT GOOD graduate school environment? We burn out. We "leak out" of the pipeline. We carry loads of responsibilities. We do service to our departments.

None of it matters if you boss is bad and doesn't give a [redacted]. You will not apply for PI jobs. You will not interview. You will not get a PI job. And if you do, you are coming in burned out and departments don't support junior faculty appropriately. It's a nightmare.

Existing NIH policies, programs, or resources

Departments should need to be accredited for the postdoctoral training abilities. You require information from departments/"schools" on their graduate training, but you do not require any such scrutiny on the postdocs. We are ALSO TRAINEES. Give a [redacted] about us and our progress and who's getting in, who's not being retained and why. IE 4.1.25 of Part II of Terms and Conditions of NIH Grant Awards—subpart A. Stop making me do your job.

Require that we make more money. We DO NOT receive enough non-monetary training/support/whatever to justify (anymore?) how little we make for highly skilled labor. Figure out how to make it make sense for those of us on the coasts and those of us in the middle.

I will give you credit for the the NIH BECOMING A RESILIENT SCIENTIST SERIES. This is great.

Proven or promising external resources or approaches

Postdocs are hired privately. NIH grant awardees/departments should need to report Postdoc applications. Without this there will never be equity in postdoc positions and, therefore, no equity at the faculty level.

Awardees/departments should be required to report postdoc retention.

Awardees/departments should be required to report postdoc separations. AND WHY. You do it for grad students!!! Why not us? PIs need to be held accountable for postdoctoral outcomes of their trainees. No amount of links to IDPs or the NPA will solve this problem. This puts the onus on the Trainee instead of where it belongs.

here's a great program being run by Chicago institutes/universities: https://chicagolanddiversepostdocrecruitment.org/

UIC is doing great stuff with a Postdoc programming office run by a person with a PhD WHO DID A POSTDOC. Instead if some person who never even been a grad student designing programming for a person they have never been (a postdoc). https://research.uic.edu/opa/career-and-professional-development/

Maybe require PIs to go to therapy, also. A lot of us are out here having to hear and process some toxic stuff from some mentally unhealthy PIs. They should be unloading on a therapist and not their Trainees. They should be learning how to deal with themselves and their emotions from a therapist. They should be learning how to communicate and empathize with a therapist. We are going to therapy to deal with their [redacted].

Again, the fixing is at the top. Stop trying to fix postdocs. Fix the PIs.

Response 1386

Perspectives on the postdoc roles and responsibilities

I find the postdoctoral position a desirable one, especially as quality postdocs are the only way to obtain high achieving professors for graduate and undergraduate research programs alike. I feel as if the position has been undersold in importance to my generation of scientists by way of the pay disparity of going to industry over a postdoctoral position.

Fundamental issues and challenges

The primary reason I do not want to be a postdoctoral trainee is because I will take a large pay cut in comparison to working for industry. This is quite a hard revelation for me, especially as professors also do not get paid competitively compared to industry professionals, as I find great joy in teaching and would be very fulfilled being a professor and continuing in academia. For me, I know the position exists and is doable, but the preventing factor is coming out of debt from undergraduate studies which has only grown in recent years to not make a salary which aligns with the investment that has been made.

Existing NIH policies, programs, or resources

Postdoctoral trainees could be included in grant funding with a minimum allowed salary or hourly wage, along with maximum allowed working hours. I find that one of the fears many students have when investigating a postdoctoral program is to be underpaid and overworked, which prevents students from having a work-life balance comparable to an industry position.

Proven or promising external resources or approaches

No response

Response 1387

Perspectives on the postdoc roles and responsibilities

Honestly, its a lot of work with very little scientific or professional development that has my own interests in mind. I was promised one thing, but now that I am here, my work is only supported if it aligns with what others want me to do, which was not what was agreed upon before I came. I wouldn’t say busy work, but its busy work adjacent, like its adjacent to the goals I wanted to pursue

Fundamental issues and challenges

I have a terminal degree and I get paid less than many people with a Bachlors degree and a couple years experience. Not to mention I moved across the country for this and did not get paid nearly enough to cover moving expenses for myself. I work excessive hours, in part because there is so little guidance or support from any one here—people check in every once in a while and the tell me things are wrong, but with out any useful feedback. This limits my social life, this limits the amount of time I have for family; taking time for those things is perceived as not being dedicated to work or being lazy. There is very ltitle reward for this work. Certainly, it is not celebrated or appreciated. What’s worse, is there is no garuntee this will get me anywhere except for behind in life. Even if I make it to be an independent investigator, the time and money that was given up to be here is not recoverable with the any potential increase in pay in future positions, though likely research will only take away pay compared to my clinical roles.

Existing NIH policies, programs, or resources

In part, the system is so big its hard to navigate. For example, this question, you’re going to give me three links to these endless pages of information and ask for specific feedback? I also have no reason to believe there will be follow up. The whole system is so disjointed, even my mentors offer conflicting advice

that is the result of not knowing how the machine works. Then once in a while, you can stumble on someone who does know something and its like, [redacted], I wish I knew that before I wasted all my time doing this other thing. Massive inefficiencies and no real structure. Even our leadership is just learning as they go.

Proven or promising external resources or approaches

better pay is promising, protected time off for health. maternal/paternal leave; actually, i would just really like to get a full set of benefits rather than have my program find ways to side step them. When it benefits them, I am clinical, when it benefits them I am not clinical, same goes with student status, or employee status. Being clinical and in a post doc position, I basically get [redacted]ed at every angle.

Response 1388

Perspectives on the postdoc roles and responsibilities

This is supposed to be a period where trainees learn the skills of getting into academia, doing research, getting grants. There has been a big shift in mentality and current postdocs are not motivated to do this. They are simply coming to do a 9-5 job knowing that they will look for another job, which often affects the collaborative lab research. perhaps different branches of postdoc training, depending on where the person wishes to go should be created with different opportunities and incentives.

Fundamental issues and challenges

In many institutions, the pressure is upon PIs to accommodate all the availability and increases in salaries, educational curriculum etc. There is no support from academic institutions in this and as a result we are forced to cut research of existing programs to accommodate the changes. But this is a serious threat to productive research that would be needed to ensure continuous fundings. We receive grants, which are seriously cut by funders and in the midst of the program we also have to further cut to accommodate salaries etc. This is not correct. We will either reduce productivity or simply cut postdoctoral positions or replace them with technicians etc. Institutions and funders need to responsibly look at mandatory regulations that impact funded research. At least provide supplements or financial support to cover these unanticipated expenses without jeopardizing research.

Beyond this it os important to consider that research is not an optional luxury. Some thinking needs to be done towards also stabilizing retention of investigators in academia. A major risk of postdocs not coming to academia is because they look at the unstable situation of being at risk of loosing a job of they do not get funded. As a result they come unmotivated as a transitional period before getting a stable job elsewhere. The whole academic system needs to be rethought and whatever policies are made you need to look at the whole hierarchy, PIs included. We are not the enemies of postdocs. We nurture them,, support them, train them but we also bear the grunt of every regulation that is sporadically made to show support towards postdocs.

Existing NIH policies, programs, or resources

provide more support to PIs to improve the postdoctoral experience. Faculty are responsible for training and sustaining postdocs but we are viewed as the reason for their fallout. Provide supplements and incentives to faculty to improve the postdoctoral experience, rather than cut down such opportunities.

Proven or promising external resources or approaches

Include faculty in your working groups with sufficient diversity to inform you. They will inform you of the gaps in academic institutional support, environment, perceptions, and postdoctoral performance. The decisions taken should not just be salary increases!!! Especially if there is no supplementary support to provide this to the PIs who offer postdoctoral position.

Response 1389

Perspectives on the postdoc roles and responsibilities

We need to move on from referring to postdocs as trainees—they are not trainees—they are trained scientists and researchers with an advanced degree and the ability to develop, manage and advance important projects. They are a critical part of the scientific ecosystem that can

a) quickly pick up new skills and techniques and

b) contribute to the scientific advancements of student/technicians/trainees and the lab itself.

With the increasing length of the PHD and the postdoc—it is unreasonable to refer to these highly trained and responsible individuals as trainees—THEY ARE A LOT MORE VALUABLE THAN "TRAINEES". Every job requires training and learning—a postdoc is no different.

Fundamental issues and challenges

With an increasing length of the PHD and the postdoc—referring to postdocs as trainees so as to not pay them what they deserve is the number one reason that there are fewer postdocs overall. With their level of skill and training and ability to grasp concepts rapidly—this is unacceptable.

The second reason is the awful work-life balance expected of these individuals—it shows that the system does not respect their skills, their time or their personal lives.

Existing NIH policies, programs, or resources

limit the length of the postdoc. And increase the pay.

Proven or promising external resources or approaches

A phd student can be hired into non-postdoc positions with better pay and better work-life balance—bring that into the postdoc ecosystem—and stop referring to them as trainees—they are highly trained and skilled—learning on the job is not unique to a postdoc position!

Response 1390

Perspectives on the postdoc roles and responsibilities

A transitory period of training designed to guide you into a career in academia

Fundamental issues and challenges

The main problem I think most postdoc face is the salary. Industry offers highly competitive salaries to do science so academia is no longer than only option for many scientists

Existing NIH policies, programs, or resources

I do not feel confident answering this question as my PhD training was done in Canada and have little experience with the NIH thus far

Proven or promising external resources or approaches

Perhaps the NIH should look into why industry is recruiting and retaining top talents and their approach can be hijacked by the NIH to do the same

Response 1391

Perspectives on the postdoc roles and responsibilities

postdoc is a training position toward an independent path. However, most of the time postdoc are not ready to be a PI at the end. There is no training in how writing a grant, how writing a manuscript. PI are expecting you to do benchwork and writing together. impossible!

Fundamental issues and challenges

Salary.

Young PI are not ready to training a postdoc. Old PIs do not have time to training.

Existing NIH policies, programs, or resources

PI who train a postdoc should be obligated to some training as well. PI often does not follow policies. For example annual evaluations of the postdoc progression, future prospection and carreer development. PI are often interested only in benchwork.

Proven or promising external resources or approaches

No response

Response 1392

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

No response

Existing NIH policies, programs, or resources

I believe that a major factor that inhibits recruitment and retention of postdoctoral trainees and early career investigators in biomedical research is the often complete lack of job/salary security associated with faculty positions, particularly in schools of medicine. The schools usually do not provide any 'hard' salary support to research investigators. If the investigator is a clinician he/she might obtain salary support to perform clinical duties that take away from time spent on research. If the investigator is not a clinician or does not want to perform clinical duties, he/she is often fully dependent on grant funding to support themselves. This is a challenging, very competitive, and stressful employment scenario; one can work countless hours on grant proposals, the funding of which is not within the investigator's control. On many occasions I have pondered why anyone would accept this type of employment scenario. I suppose it is a fantastical proposition, but I believe more extremely competent individuals would consider and be retained in biomedical research careers if NIH/funders funded researcher's salaries separate from (or instead of via) the competitive grant proposal submission and peer review process. Obviously, this would be a radical change from a long-standing tradition and would require much thought about how research proposals are conceived and how funding decisions are made while still supporting novel, researcher-initiated ideas. But, if anyone is genuinely interested in improving the quality of life of biomedical and other researchers, providing some degree of job/salary security (e.g., in exchange for a certain level of expected scientific productivity) would go a long way towards achieving that goal.

Proven or promising external resources or approaches

No response

Response 1393

Perspectives on the postdoc roles and responsibilities

It is an essential training and enable dedicated support to develop my own research expertise. It is necessary for an academic career in research.

Fundamental issues and challenges

The biggest challenge is finding the right fit for my postdoctoral training. Often postdoctoral training opportunities are not marketed and often are limited to a local pool. I wished for a national "database" accessible easily so that I can search to do a best-match. Second, postdoc salaries are low and relocation to the best fit training opportunity is an out-of-pocket expense.

Existing NIH policies, programs, or resources

Administrative Supplements to Promote Research Continuity and Retention of NIH Mentored Career Development (K) Award Recipients and Scholars could be expanded to include time taken off for mental health care, meaning it is not just time off to take care other people but take care of themselves. Academic research is very intensive and raising a family the same thing is very stressful. I am undergoing divorce. I wish divorce could count for critical life event.

Proven or promising external resources or approaches

Mentoring is the most important aspect of my postdoctoral training. CTSI resources are also essential. For an example, peer review program, https://ctsi.utah.edu/cores-and-services/about-us/peergr

Response 1394

Perspectives on the postdoc roles and responsibilities

It mainly means the transitional stage to a more permanent academic position for me.

Fundamental issues and challenges

I cannot stress enough the the need for NIH postdoc pay scales to be adjusted to market in each city rather than being seen as a national standard applicable to each university in the country. In the name of this NIH scale, many universities, including some Ivy League schools, underpays its postdocs. We must immediately set the NIH minimum postdoc salary at 65,000 USD.

Existing NIH policies, programs, or resources

Equitable pay and a friendly visa regime for international postdocs are the two key issues. Those foreign students with an US PhD should be sponsored for H1b visas by their institutions and the NIH should include this in their policy recommendations.

Proven or promising external resources or approaches

MIT postdocs have won some benefits and salary increase recently, as did Princeton postdocs. both might be good models for changes in the postdoc policies.

Response 1395

Perspectives on the postdoc roles and responsibilities

The primary role of a postdoc is to prepare for their next career stage. This involves comprehensive training in managing people, mentoring, grant writing, paper writing, adherence to advisory councils (IRB, IACUC etc.), and many more skills that would apply to someone interested in an industry position (which I am not).

Fundamental issues and challenges

The fundamental challenges for postdocs are compensation, academic culture, and high expectations leading to burn out. Established faculty that follow the dogma of "I endured it so you shall, too" are shooting themselves in the foot. PhD graduates are recognizing that the inherent stress of academia (competition for funding and publications, need to "self support" salary with grant money, low salaries relative to market) is not worth enduring if there is no indication for a cultural shift in how postdocs are trained and compensated. For example, my institution does not have: standardized contracts for postdocs (they are different across every department), clear expectations for the way faculty will mentor postdocs (if postdocs are going to be compensated as "trainees" they deserve comprehensive scientific and career mentoring), formalized methods for requesting time off, or a centralized system for postdocs to raise concerns to leadership. The lack of formal support creates an environment that exploits the most vulnerable (financially strained, systemically marginalized, international).

Existing NIH policies, programs, or resources

Expand support for child-care expenses as part of training awards, offer specific awards aimed at covering child-care expenses for academic professionals. Open all training grants to domestic and international individuals. Increase the rate of review for postdoc grants, as it stands right now a K99 application will be funded about a year out from submission. This system might work okay for a faculty member, but the time delay significantly impairs the number of grants a postdoc can apply to during their limited position. Also open more funding opportunities like the NCI early-stage K99 that promotes a swift transition to independence. Increase the NIH-mandated postdoc minimum salary (which we all know acts more like a maximum salary for many).

Proven or promising external resources or approaches

Require CIMER training and annual recertification for all faculty that hire postdocs on NIH grants.

Response 1396

Perspectives on the postdoc roles and responsibilities

Postdoc means working incredibly long hours, sacrificing time with family and friends, for very little compensation with little encouragement about future career prospects.

The idea of having to compete brutally for increasingly limited funding is a serious consideration when I consider future plans.

As a female postdoc, to me it means working 2X as hard as male colleagues for the same—or often for much less—credit and recognition.

I love science. I'm very interested in my field. I love working with students and mentoring them. I want to be academic faculty. A postdoc should be a time to prepare me for that.

But it's so stressful and uncertain.

It is also INCREDIBLY difficult to be a pregnant postdoc.

Fundamental issues and challenges

We aren't paid enough and we don't have maternity (parental) leave. We are critically undervalued. As a female postdoc I feel that I have to work 2X as hard to be recognized or heard. My contributions are often sidelined. And I'm in a good lab, at a good institution with funding. Sometimes I think that I'd rather go to industry, because at least I'd be paid more to deal with what I have to deal with everyday.

Adding to that—for the last 5 years, at every conference I've been to (large ones, like BPS) people are actively discouraging graduate students from doing postdocs, saying that there's no faculty positions and that it's hopeless. This is done in large career focused sessions.

I think people have figured out that a postdoc is overworked, critically underpaid and undervalued. And they don't want to do it.

The outlook for me as a postdoc is daunting.

Existing NIH policies, programs, or resources

F32 needs to provide better benefits for parental leave. Leave absolutely must be paid, at a minimum of 12 weeks. We need support and resources for pregnant and new parent postdocs. Issue guidelines for the aforementioned that universities need to follow.

We need to be paid more.

Anything at all to help with the following—I do not want to feel shut out from science because I am pregnant. I feel that there is almost no support for me. It has been so, so difficult.

Any increases in postdoc fellowships would be welcome. Sustained focus on efforts for mental health and outreach.

Proven or promising external resources or approaches

Improve our pay, benefits, and PAID parental leave. Improve mentoring of female and underrepresented trainees. Require bias training. My mentor is a really good person. I don't think they truly realize that they treat me so unfairly compared to male colleagues.

Additional support for pregnant and new-parent postdocs. It is our right to have a family. There is almost no support.

I wish I could say that I was aware of more current efforts to improve things but I'm not. I'm encouraged that NIH is doing this survey. I would love to see things improve for us in academic science.

Increase available funding for postdoc fellowships and for faculty level research. It's difficult to keep going when faculty futures seem so bleak.

I have heard trainees say that the NIH (OITE) mental health awareness-focused sessions are good. Thanks for those!

Response 1397

Perspectives on the postdoc roles and responsibilities

The idealized goal of the role of a postdoc is that it is an opportunity to receive advanced training, often relating to learning new skills, and to have time and space to develop a more independent research program. This typically would involve directing their own research projects while receiving support from the PI, as well as potentially assisting in mentoring trainees, such as graduate students. The typical postdoc experience is of course rarely anything like this. PIs treat the role as cheap labor to fulfill their own research goals, and rarely provide any meaningful amount of training or mentoring. What should in theory be a short term contract for an amount of time useful to learn new skills can instead often trap people in indefinite timeframes of underpaid and abusive work.

Fundamental issues and challenges

Postdoc positions are drastically underpaid, related to our training, skillsets, **and responsibilities**. The National Institute of Health bears a direct responsibility for this—it's granting schemes have been reducing in real-dollar values for decades, squeezing lab budgets. It's pay scale recommendations are insulting. The stipend for the F32 is too low. The NIH has been asleep at the wheel for ensuring that scientific research staff are trained, supported, and have opportunities for adequate employment. Academia also has rampant issues relating to power-based harassment, bullying, and sexual-harassment, which the NIH has also done next to nothing to meaningfully address. Given the range of problems that are so deeply ingrained in academic research, I find it difficult to recommend to others that they should pursue this path.

Existing NIH policies, programs, or resources

Fix the pay scale, make clear how it is expected to be used, and make clear that there needs to be cost of living adjustments. Tie all pay-scale guidance to cost-of-living, and make it clear that adjustments should be made based on local cost of living. Increase the amount of funding available in a modular R01 such that lab budgets can adapt to paying researchers and students appropriate to their skills. When reviewing grants, enforce that a budget line item for postdoctoral researchers whereby the total compensation is below adequate cost of living is considered unacceptable and will be rejected. Institutions and individual PIs who are found to be involved in illegal harassment, including sexual harassment and bullying at the level of individuals, and workplace violations including retaliation to whistle-blowers and illegal retaliation against union activity should be strongly condemned and face consequences, including having funding removed and being restricted in applying for new funding calls.

Proven or promising external resources or approaches

As a research institute, I assume you should be fully capable of finding and reviewing the existing evidence on the benefits of paying people a living wage, and the benefits of keeping working hours under control, and removing abuse from the workplace.

Response 1398

Perspectives on the postdoc roles and responsibilities

For me, the academic postdoc was critical for obtaining a faculty position. It provided me with an opportunity to gain new skills, refine my interests, and build my professional network.

Fundamental issues and challenges

The biggest issue with the current postdoc model is low pay. I was a postdoc at [redacted for anonymity], and the NIH minimum for postdoc salaries there puts postdocs under the poverty line. This is further worsened by those with caregiving and childcare responsibilities. The low postdoc pay is acting as a gatekeeper, as those who can afford to stay in postdocs are those who likely have family money or are otherwise well off.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1399

Perspectives on the postdoc roles and responsibilities

A postdoctoral fellowship is an opportunity to acquire and develop skills necessary to career goals, to gain a new depth/breadth of knowledge in a given field, to expand ones scientific network.

Fundamental issues and challenges

Financial. Work-life balance. Abuse from PI—this is one career where our career success is tied ever so closely to our PI (recommendation letters, opportunities, attention), so that creates an environment conducive to abuse. Career stability in future academic positions. International postdoctoral fellows need more protection since the lack of stability in VISAs can make them vulnerable to abuse. I know of many postdocs that are stuck in their lab and cannot leave the country because of poor VISA management—both on the institutions behalf and the postdocs.

Existing NIH policies, programs, or resources

Establish a program that ties the PI more closely to a postdoctoral students success. Something that shifts the responsibility of a postdoctoral success to the PI, so that they are more invested. For instance, if a postdoctoral fellow is working science funded by an NIH grant, make it NIH policy that the PI must reach/achieve certain career milestones for a given postdoctoral fellow to demonstrate the PIs investment in the postdocs career (manuscripts, conferences, networking opportunities, letters of recommendation). This should be something that is demonstrated on a continual basis, but not too taxing for PIs.

Increase pay. Increase maternal/paternal leave. Increase rights around VISAs/VISA renewal—institutions should be more involved in educating and maintenance of VISA status of international postdocs. If not, postdocs will eventually unionise.

Proven or promising external resources or approaches

No response

Response 1400

Perspectives on the postdoc roles and responsibilities

Postdoctoral positions are critical to establish a stratified hierarchy of each individual laboratory. This model allows each member of the team to learn about the collaborations, critical thinking, learning process, troubleshooting, academic ladder and alternate options. The teamwork is today more critical than ever; however, it is important to assure autonomy of each individual team member towards their goals, i.e. to meet and exceed the expectations for first author papers and contribute to other projects, including both internal and external collaborations. For principal investigators, the long-term measure of their success is what their postdocs learned within their team and how their subsequent careers were positively influenced by 3-6 years of their trainings. Positive feedback is the increasing reputation of the principal investigators. In life sciences, it is inevitable that some projects require weekend efforts and commitments that remain under appreciated. The postdocs are expected to work independently and flexible arrangements between them and their PIs should be available. The range of intense daily dialogues over a couple of weeks at one side and independent creative progress with just informal statements "everything is moving well—just started to draft my paper—have exciting data for the next lab meeting, just one more control experiment" over a period of 6-8 weeks.

Fundamental issues and challenges

The overall quality of life of postdoctoral trainees remains unresolved. There are at least three areas that need attention.

1. The stipend levels are below salaries of undergraduates requiring less skills. In addition, no retirement benefits are included. Thus, following 5+ years as graduate students and another 3-6 years of postdoctoral training without this critical benefit is a major inhibitor for this professional career.
2. The gap between "top" 25 research universities/institutes and the representative "median" college/university has significantly increased during last 15 years. While the accomplishments of the leading institutions are applauded it is necessary to help other universities and their postdocs with comparable opportunities in synergistic training involving bench experiments, multi-omics, and computational biology & bioinformatics. The current pace of newest and improved technologies is very positive but a project near completion using state-of-art methods defined for this purpose 2-3 years earlier is often challenged by a set of newest, more expensive technologies, only available to a limited number of labs who ultimately outperform others given the total collection of their primary resources.
3. A major portion of postdocs is represented by international graduate students who received their PhD in the US-based institutions together with PhDs from a range of countries with main contributions from mainland China and India. As they pursue their professional dreams in the US, they are willing to sacrifice their inadequate financial support for once-per-life opportunity to work at the best institutions with our leading scientists solving the mechanisms of human diseases and finding new therapies that benefit patients in need. This is not sustainable in the future.

Existing NIH policies, programs, or resources

The current policies regarding postdoctoral training are efficient; however, bottom line is the total NIH budget. An average R01 budget needs an increase to accommodate sufficient staffing, overlaps between senior postdocs and junior graduate students and adequate support of the PIs, especially those on soft money budgets.

Proven or promising external resources or approaches

The NIH may consider to establish a new "support center" on its Bethesda campus. This center will organize 2-4 day long diverse classes to teach postdocs certain skills such us job hunting, preparing the K99/R00 and R01 awards, hear talks from inspirational academy and industry leaders, learn how to negotiate the job, and etc. Poster session showing their research should be included in the program. In parallel, meeting 50-100 fellows will promote mutual networking and sharing experience. If there are +50,000 postdocs in the biological and biomedical sciences, health, and clinical medicine in the US, with 60% depending on grants, this looks like a good long-term investment.

Response 1401

Perspectives on the postdoc roles and responsibilities

It's supposed to be a time of further training and independence as a new researcher. For me, it ended up being mostly babysitting with limited academic freedom.

Fundamental issues and challenges

Payback clauses are terrible—no one should be forced to stay in a position they hate. Overall there's a view that the postdoc can take care of all the younger people in the lab, but that takes away from what the postdoc is supposed to be doing. Recruitment of poorly qualified postdocs who just want to get into the US and will apply to anything further takes away from a good postdoc's experience. Compound that with the fact that a postdoc can work for a university for years without ever getting retirement benefits, and you have a situation where good people just feel like they're being used.

Existing NIH policies, programs, or resources

I can't take the time to read all of that, but if universities in places that don't normally get a lot of postdoc interest want to recruit better people, they need to up the benefits. Retirement (+ match) and free parking would be a start.

Proven or promising external resources or approaches

No response

Response 1402

Perspectives on the postdoc roles and responsibilities

investigation of different hypothesis, finding significant relation between new variables, publishing their achievements.

Fundamental issues and challenges

1) Professor's psychological issues. if you ask from the postdocs that have M.D degree, they will report to you that lots of professors have psychological problems. and its ok till it doesn't hurt others but sometimes it w.
2) Economical problems
3) Insufficient or inadequate scientific achievement in a period of time.
4) Not seeing the postdoc's effort.
5) Adding lots of stranger's names on their articles.

Existing NIH policies, programs, or resources

More support against sexual abuse. Some professors have power, money and relations. some postdocs cant report their problems.

Proven or promising external resources or approaches

Don't keep psychological ill professors in your departments. They will sexually abuse their students and the postdocs will get depression and will do suicide, special for postdocs that are foreigners (on Visa) and don't have the situation to go back to their country because of war or other things.

Healthy professors and postdocs should write feedback to each other every 3 months. Please teach to your professors to how to listen and how to talk politely. Don't insult, don't physically touch, don't tell to your students that I will do all of these things and you should be silent.

Response 1403

Perspectives on the postdoc roles and responsibilities

This position was a chance to directly manage projects and train to be a full scientist under direct mentorship of a supervisor.

Fundamental issues and challenges

Supervisor just views me as another worker. Was not provided any additional support and was expected to know everything when I first joined the lab.

Existing NIH policies, programs, or resources

Proven or promising external resources or approaches

Force all postdoc positions to follow NIH pay guidelines to make the postdoc career path enticing and affordable to families

Response 1404

Perspectives on the postdoc roles and responsibilities

A postdoc is a highly skilled researcher in a position that should facilitate increased independence and skill development. Postdocs are integral to the function of large biomedical research labs and often lead complex data analysis, mentor graduate students, and write grants.

Fundamental issues and challenges

Money. This is a straightforward issue with a straightforward solution. Current postdoc salaries are not commensurate with the level of skill and experience that is required. With so many lucrative career paths in the private sector and the volatility of the academic job market, for many people it simply does not make sense to pursue a postdoc position.

Existing NIH policies, programs, or resources

NIH should increase its payscale for postdoctoral researchers. Academic institutions seem to almost always adhere to this payscale by default, and so NIH has a lot of influence on how much postdocs are paid across the country. Unfortunately, this rate is not often adjusted for factors like cost of living. It also has not been adjusted for inflation and increases in the cost of living over time. My understanding is that this pay scale has not substantively shifted in many years, exacerbating the underpayment of postdocs and minimizing interest in these types of positions.

Proven or promising external resources or approaches

No response

Response 1405

Perspectives on the postdoc roles and responsibilities

A postdoc is an opportunity to continue producing academic research while hopefully preparing for the next phase of the individuals career (tenure faculty position, principle investigator, industry researcher, etc.)

Fundamental issues and challenges

The astoundingly low pay is the biggest challenge to postdocs at the moment. Academic researchers dedicate themselves to the advancement of the world around them and are not adequately compensated to even survive. The amount of work and the low pay expected from postdocs is one of the most toxic and abusive aspects of academia. This is likely one of the biggest reasons why people leave academia in combination with the lack of job prospects as a principle investigator or some other leadership role in academia.

Existing NIH policies, programs, or resources

Pay postdocs a living wage

Proven or promising external resources or approaches

No response

Response 1406

Perspectives on the postdoc roles and responsibilities

Secondary experience, mid-career opportunity before starting a lab.

Fundamental issues and challenges

Too high of expectations for too small of a salary, given the education level. Relative lack of job security, given lab funding.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1407

Perspectives on the postdoc roles and responsibilities

Depending upon the lab composition, an academic post doc holds may be the most responsibilities in a lab set up right after the PI. Starting from project management to lab management to mentoring, personal and professional development-a post doc has to fit in many shoes. Sadly so, a post doc is not provided by with the job security and compensation which might be deserved for someone fitting into so many roles, often making this to be a position which is accepted as being a transition state before moving to more promising secure opportunities outside of academia with better work life balance and meaningful compensation. For an individual at the prime of both their professional and personal lives, unfortunately this position seldom provides the peace of mind in the United States, as not only a post doc is at the complete mercy of the supervisor but often their are no structured policies even for a post doc to tackle issues.

Fundamental issues and challenges

Currently the lack of interest probably comes from the disillusionment stemming from the low quality of life associated with the profile. Specially after covid, which showed the importance of so many "taken for granted" things in life—mental health, spending time with family, personal care—investing so much time and effort and energy in a profession which in return provides so little fulfillment of basic necessities, individuals for whom being in academia isn't set in stone, they are choosing different paths. Of course for people coming to the US from abroad, a different path isn't an option due to immigration policies, or may be for whom, maintaining immigration status is a necessity-these people often remain post docs just to make use of the time until a better opportunity opens up. This often ends up with a general lack of motivation or appreciation for the profession since apart from that small stock who actually wants to be an academic, the profession is populated with disgruntled post docs who often elaborate their experience to there peers in the community which may be also adds up to the general lack of interest. An attitude of "we did it the same way, so can you"—as often phrased by the seniors in the field doesn't help since times have changed, and everything comes at a higer price as it did 5/10 or 50 years back.

A fair centrally controlled recruitment—similar to grad student recruitment, stating proper information regarding compensation, working hours, resources available for post docs might help? This also curbs the power of certain PIs who tend to exploit their post docs due to lack of transparency associated with the whole system.

Existing NIH policies, programs, or resources

Though some institutions try hard to honor policies to aid post docs, but still I know many universities/ institutions in the US which fail to provide so. Many of the post docs are immigrants like me come from a completely different nation, to gain best quality scientific experience in the US. It is sad when they get recruited in labs where they are not even compensated at the NIH scale. I have heard instances where the supervisor had mentioned that they have to work on the weekends or holidays if they want to get paid in accordance to the NIH scale. Or the incoming post docs are recruited at lower compensation than the scale.

Requesting leaves, are a whole new story. Lack of policies like paid and unpaid leaves—as provided to any staff or employees in other professions results in being reprimanded or not paid if they take some time off.

Lab timing—since post docs are not clocked in—most of the time they spend longer hours without weekends making them vulnerable to emotional and physical burn out.

Lack of basic rights—a colleague on J1 visa, was refused maternity leave in her lab, leading her to change her lab at sucha critical juncture in life.

Often an unofficial hierarchy exists in some labs, wher "bullying/emotional exploitation" remains uncomplained—as one is at the mercy of the PI for professional interest like recommendations, immigration; since if one has to change labs—the individual might have to deal with change of status and what's the guarantee that the next lab won't end up being the same as THERE ARE NO POLICIES.

These are basic necessities/rights a working individual should have in a professional set up—but we as a community lack our basic rights.

Proven or promising external resources or approaches

We need basic policies

We need

1) job security
2) work-hours which is reflected in compensation
3) aid to help post doc fight against oppression in the lab
4) resources to help with child care, mental health, comprehensive medical insurance
5) proper leave and clocking in and out
6) proper increments
7) a post doctoral committee to help with recommendations in case there is a falling apart with the PI
8) the PIs need to be educated to manage labs and people
9) We want to be valued for our efforts, for our hardwork and not being treated like machines to get more data.

If there is a properly structured transparent post doctoral recruitment and support system available which can promise a fair compensation and work life balance—people would be motivated to do science. It doesn't help when we see people with basic/vocational training or from other fields working 9-5 jobs and earning double or triple the amount than we do. It just makes not value the big picture science anymore but question our professional choices in the first place! Unhappy professionals cannot help in driving something for long. It is unhealthy for that individual and also for the profession.

Response 1408

Perspectives on the postdoc roles and responsibilities

An academic postdoc presents a great opportunity for me as it provides a platform to build and develop the necessary skills for being a successful independent investigator. Opportunities to interact with other fellows and the research community are extremely valuable and beneficial in discussing novel ideas, troubleshooting, finding collaborations, and networking. The mentorship support provided by a senior scientist in the field is indeed a great way to shape and refine my research project. In addition, virtual group seminars, workshops on leadership skills, and grant writing support are the things that I look forward to learning to make a smoother transition from my current role as a postdoctoral researcher to set up an independent and well-funded research program in the future as a PI at a reputed institution.

Fundamental issues and challenges

I really enjoy being in academia as a postdoc. The only constraint that I feel is with the stipend/salary as it's way lower than an Industrial post-doc would offer. I am thinking of moving to Industry only because I am not able to fulfill the family needs on a postdoc salary. There are no additional compensations for child care, dependents, etc. This overall diverts my focus from research to managing finances.

Existing NIH policies, programs, or resources

I believe raising the minimum salaries for post-docs and providing compensations like dependent care, child care, etc. would definitely enhance the quality of post-doc life in academia. I see many of my peers moving to Industry just because they get better salaries there. Instead, appropriate training should be provided to postdocs who would like to stay in academia.

Proven or promising external resources or approaches

Once postdocs are satisfied with the salaries, they will be more productive leading to better outcomes.

Response 1409

Perspectives on the postdoc roles and responsibilities

A postdoc should provide focused experience in their future research area; and have ample support for data analyses, data dissemination, and grant writing. How much is gained from a postdoc can greatly vary, and the quality of the postdoc mentor largely determines success.

Fundamental issues and challenges

Pay is too low. We are paid a subpar salary for years and treated as such. The fact that the pay scale does not take into account cost of living or inflation makes no sense. We have doctorates and are paid worse than most individuals working hourly jobs. It has become fairly common to complete 2 postdocs before getting your first faculty position, which means moving every other year, resulting in a lack of social support and financial stability. Moreover, as someone who comes from a disadvantaged background, current policies where individuals are not provided with moving expenses is classist. This restricts the ability to cast a larger net for postdoc opportunities to those who have the advantage of financial support from family, restricting future professional growth. This is especially disappointing given the NIH focus on diversity and inclusion. For me personally, I supported myself entirely though undergrad and grad school, so on top of my large amount of student loan debt, I have credit card debt because that was the only way to move for my 2 postdoc positions. I came from generational poverty and thought a doctorate would provide me with financial stability, but so far, I have incurred an incredible amount of debt and a lack of financial support.

Existing NIH policies, programs, or resources

I will reiterate my above response for consideration: Pay is too low. We are paid a subpar salary for years and treated as such. The fact that the pay scale does not take into account cost of living or inflation makes no sense. We have doctorates and are paid worse than most individuals working hourly jobs. It has become fairly common to complete 2 postdocs before getting your first faculty position, which means moving every other year, resulting in a lack of social support and financial stability. Moreover, as someone who comes from a disadvantaged background, current policies where individuals are not provided with moving expenses is classist. This restricts the ability to cast a larger net for postdoc opportunities to those who have the advantage of financial support from family, restricting future professional growth. This is especially disappointing given the NIH focus on diversity and inclusion. For me personally, I supported myself entirely though undergrad and grad school, so on top of my large amount of student loan debt, I have credit card debt because that was the only way to move for my 2 postdoc positions. I came from generational poverty and thought a doctorate would provide me with financial stability, but so far, I have incurred an incredible amount of debt and a lack of financial support.

Proven or promising external resources or approaches

No response

Response 1410

Perspectives on the postdoc roles and responsibilities

I view a postdoc position as a “soft entry” into a tenure track position in academia.

Fundamental issues and challenges

I am nervous that the postdoc positions will not pay nearly as well as a junior faculty role, which can be inhibiting to those of us who have been living on ~30k salary of full-time graduate students

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1411

Perspectives on the postdoc roles and responsibilities

The roles and responsibilities of the position entail a much broader range of activities to that of graduate students, even though it is often not treated as such. Postdocs who wish to remain in academia must devote a portion of their time honing skills like writing grants and research proposals, but also teaching and mentoring junior trainees, all the while coming up with a viable and independent strategy for future research. This is often ignored by senior researchers and principal investigators who see postdocs as a cheap work force attending only to their immediate research visions.

Fundamental issues and challenges

Given the recent inflation and hike in prices, the quality of life has degraded substantially, and many of us feel the postdoc salaries should be adjusted to meet the demands of the economic present. Otherwise, more and more people will put into action their plan to drop out, something many are already seriously considering.

Existing NIH policies, programs, or resources

NIH should raise the minimum salary for postdocs.

Proven or promising external resources or approaches

No response

Response 1412

Perspectives on the postdoc roles and responsibilities

Postdoctoral positions are largely research focused and provide additional experience. However, if this experience is not needed due to previous training, there are limited alternate routes. Further, it is typical for any career to involve on the job training, so it is not clear why this phase is prolonged and underpaid for postdoctoral scholars. As a clinical psychologist, the position is beneficial in allowing me to accrue clinical hours under a licensed psychologist.

Fundamental issues and challenges

Underpaid given expertise and contributions, especially within research spaces. Limited advancement to assistant professor positions within Psychology Departments. Negatively effects lifetime earning potential and ability to purchase a home or start a family.

Existing NIH policies, programs, or resources

Proven or promising external resources or approaches

Improving recruitment, providing smaller and more vast training supplements for postdoctoral trainees with lesser application requirements. This may help overcome differential access to well-funded mentors and collaborators that guide the federal-funding application process.

Response 1413

Perspectives on the postdoc roles and responsibilities

The postdoc position represents an opportunity to further develop one’s research skills in a particular area while gaining additional leadership experience. Responsibilities may include leading research projects, mentoring students, and applying for funding. By the end of a postdoc, one should feel ready to independently lead their own research program.

Fundamental issues and challenges

In my view, low salary and low likelihood of success on the academic faculty job market are the two biggest issues impacting recruitment, retention, and overall quality of life. The current annual increases in salary do not come close to keeping pace with inflation and are not competitive with non-academic positions. It seems hard to justify ~5 years of low pay in a postdoc position when the odds of obtaining a

desirable (i.e., tenure-track, at a reputable institution with adequate resources) faculty position are small, and one might have greater success on the non-academic job market without doing a postdoc.

Existing NIH policies, programs, or resources

Higher salary levels; greater annual salary increases.

Proven or promising external resources or approaches

I'm not sure exactly what form this would take, but it would be helpful to incentivize PIs to care more about their postdocs' career trajectories.

Response 1414

Perspectives on the postdoc roles and responsibilities

To me the postdoctoral position is a combination of training in new disciplines and research. We are the fundamental drivers of research in a university setting as we have the knowhow that graduate students lack and we work full time (I work >60 hours weekly averaged over the year) on experiments and data collection, unlike the professors who write grants, teach, and can frequently be very far removed from the lab.

Fundamental issues and challenges

For a person of my training (physics, data science, biology), it's not hard to find an industry job upon obtaining a PhD with an initial salary of 2X greater than what I am currently making. For a year or two this is ok, but with postdocs stretching longer and longer, this becomes very difficult. I'm in my sixth year now, I've started a family, and this year in particular I've had to take out loans. In other words, I am borrowing money to fund my postdoctoral period, as an investment in my future career. This financial pressure is so unsustainable that I will leave next summer, regardless of what is finished. Thankfully I am close to two sets of results. However, I am currently the only one in the building who knows how to use the system that I built (which cost > 1 million dollars). If I have to leave earlier than next summer because of financial pressure—will all of that be lost because my salary is insufficient to support my family?

Existing NIH policies, programs, or resources

The NIH should move towards funding 3-5 year contracted staff scientist positions with salaries competitive to those in industry, but without long-term stability (i.e. tenure). `Postdoctoral training' originally meant 1-2 years and then a decent chance of an academic position. Now it means > 5 years and low chances of an academic position, on top of a poor salary. If one understands the resulting financial pressures—who would sign up for this? On the other hand there are many people interested in doing science if the salary keeps up with what is reasonable (i.e. industry standards), and are willing to work on untenured track positions. Separately, the NIH should certainly increase existing postdoc salaries and in general remove salary limits on postdocs—if a PI wants to pay a large amount of money to a postdoc, why stop this? Surely laboratories should be competitive with industry, especially when long-term prospects for tenure-track jobs are low.

Proven or promising external resources or approaches

No response

Response 1415

Perspectives on the postdoc roles and responsibilities

A final training experience to prepare you to become tenured faculty or a scientist in an industry role

Fundamental issues and challenges

Too many years of training (the increasing expectation of completing two postdocs), salaries are way too low for a doctoral level scientist (why do a postdoc when you can go into industry and make 3x the salary), PI expectations of work hours are too high

Existing NIH policies, programs, or resources

Increased grant funding to allow increased postdoc salaries in academia; NIH mandated postdoc salaries should increase

Proven or promising external resources or approaches

No response

Response 1417

Perspectives on the postdoc roles and responsibilities

The post-doc remains an essential period of apprenticeship toward sustaining our position of excellence and leadership in global biomedical research (perhaps not so much any more). Training in biomedical research is not like training in business's nd it is being viewed and managed increasingly as if it is. This is a disaster, and I am very concerned about the future of our profession.

Fundamental issues and challenges

First and foremost, the goals expressed by a working group several years ago that created the rapidly escalating post-doctoral salary scale have been achieved—see the text in the introduction to this RFI. An express goal (I was at the meeting) was to reduce the number of post-docs in the biomedical research workforce as there was at the time apparently a perceived glut and bottleneck to professional advancement at the level of the post-doc. This was to be achieved by pricing them out of a job, to make them too expensive to keep in the lab and therefore force them to seek employment outside the intended career trajectory (I repeat, I was at the meeting where the white paper was presented by this task force). It has worked, and we are now in the dumpster!

Existing NIH policies, programs, or resources

If NIH is going to continue to insist on forcing an escalating and unreasonably burdensome pay scale for post-docs (including entry level), and if the current academic and social climate continues to encourage business-oriented initiatives like post-doc unionization and work stoppages, the publicly funded biomedical research initiative is doomed to self-inflicted failure. We can't put the toothpaste back in the tube, but two things may help if implemented immediately—

1. FREEZE the current post-doc pay scale for a period of several years, and gradually trim the rate of escalation esp after year 3, and;
2. SUBSIDIZE all post-doc salaries through supplements to existing and future R01s and other research grants on which they are paid. Then figure out how to incentivize PIs to hire post-docs, because right now the perception is that post-docs are, generally speaking, not worth it (again, an intended consequence).

But we all know that post-docs are the engine of our research enterprise, and they must be saved if we are to save their future and the future of our profession!

Proven or promising external resources or approaches

The primary answer to this self-created problem is money. More T32's, more F32s, more supplements to R01s earmarked to subsidize post-doc salaries. More money for transitional grants (K99/R00) to assist them move into independent positions and hopefully offset the prior initiatives that moved them out. We all saw this coming, and now that it's here, we have no-one to blame but ourselves (and I use "we" very broadly because there is blame to be laid.)

Response 1418

Perspectives on the postdoc roles and responsibilities

I view it as the next step in my scientific training. I hope to remain in academia so I know that this part of my career is really important for my overall goals. I see the postdoc as gaining more independence in their research, honing in on the questions they might want to explore in their own labs, and working on teaching/mentoring of junior students.

Fundamental issues and challenges

Pay! I have a dream of being faculty, but I know that until that happens I cannot expect to make a living wage or have long term benefits to help me in my life. I know that I don't have a retirement account through my employer like my peers would, and I am not given student loan deferment as a postdoc, so much of my meager pay will be going to those major expenses. How can you expect people to want postdocs when industry will give you all of that and more?

Existing NIH policies, programs, or resources

Create a new way to encourage older PIs to retire. That way, people going after postdocs feel like they could actually achieve their job goals. I also think adding more personal things to the F32 to help support retirement benefits, increased pay, and student loan benefits, and healthcare will also provide a path to financial stability for postdocs.

Proven or promising external resources or approaches

Unknown, I'm just a PhD student considering a postdoc in the future and what I've mentioned about financial things is one of the biggest things I'm scared of.

Response 1419

Perspectives on the postdoc roles and responsibilities

The postdoc to me is a necessary step towards my goal of finding a tenure-track academic research job.

Fundamental issues and challenges

The main issue I have witnessed among my colleagues and peers inhibiting recruitment and retention is the low pay compared to the pay available in industry, which is often double or triple the NIH base pay. Particularly in urban areas such as NYC, Boston, and SF, it is not practical to live on postdoc salaries, often forcing people to pursue industry jobs to support their families.

Existing NIH policies, programs, or resources

Increased base NIH pay and an automatic adjustment matching inflation.

Proven or promising external resources or approaches

No response

Response 1420

Perspectives on the postdoc roles and responsibilities

Postdocs are essential to lab research—they bring new ideas, expertise and enthusiasm to a lab

I don't think postdocs should be involved in teaching, but some of them seem to be interested in teaching, perhaps in preparation for an academic job. I am not sure what the solution for this is, but I would not want to pay a postdoc from my grants in order for them to teach.

Fundamental issues and challenges

The main challenge for recruiting postdocs is financial. The postdoc salary is borderline inhumane. Many PhD students don't want to continue in academia because they cannot imagine making a living and paying their student loans from a postdoc salary. Also, many postdocs delay or forego starting a family because of lack of resources.

So I encourage higher salaries for postdocs, but I want there to be extra money in NIH grants for postdocs. Otherwise, we risk drastically reducing the number of postdocs.

Existing NIH policies, programs, or resources

I think the eligibility window for K99/R00 needs to be expanded. In some fields, it is impossible for postdocs to get enough results in 3 years to apply for a K grant.

I think there should be an incentive for PhD students to continue in academia. For example, the F99/K00 grant should be opened up to all PhD students, not only minorities.

Proven or promising external resources or approaches

We started a postdoc recruitment day, but we are limited by access to institutional funds. Perhaps there could be a mechanism to apply for NIH funds in order to finance this kind of recruiting activities.

Response 1421

Perspectives on the postdoc roles and responsibilities

The purpose of performing a postdoc is to further one's scientific training, with the end-goal of moving on to another position in academia or industry.

Fundamental issues and challenges

The fundamental issue is that doing a postdoc is not attractive because the salary is low and the benefits are mediocre.

The rewards for doing a postdoc are not materially useful. The position is generally just a stepping-stone for entering the professoriate.

Existing NIH policies, programs, or resources

If the NIH wants to make it attractive to do postdoc work then they need a strong incentive to compete with industry careers. Perhaps after 3-5 years, a postdoc has the opportunity to apply to become a government employee / researcher, where they are directly paid by the government and not from nebulously expiring PI grants.

Proven or promising external resources or approaches

Typical corporate careers have some kind of progression with promotions, salary raises, and yearly bonuses. Postdocs have none of these things because it's a dead-end job. It's one external example that could inform the NIH of how employees like to be treated.

Response 1422

Perspectives on the postdoc roles and responsibilities

Postdoctoral fellowships are critical for giving early stage investigators the time to immerse themselves in a specialized topic with significant levels of supervision from more senior investigators. Its a time to really define cutting edge research topics and opportunities, to develop professional relationships and to define your major interests, free from other academic responsibilities that come with academic appointments.

Fundamental issues and challenges

Current challenges include salary levels are very low, particularly in cities like NY or LA or Boston that are expensive to live in and particularly for PHDs vs MDs. Moreover, training grants do not support faculty time including leadership time and thus faculty do not have paid dedicated time. This is a critical barrier to really being able to provide the support post docs often need. Academic institutions just do not increasingly support this time.

Existing NIH policies, programs, or resources

Support faculty in their mentoring time, increase salary levels. Fellowships need to respond to changing world, changing academic support for these activities.

Proven or promising external resources or approaches

No response

Response 1423

Perspectives on the postdoc roles and responsibilities

The roles and responsibilities of a postdoc include

1. conducting and publishing mentored research with increasing independence and
2. providing mentorship and supervision to graduate, postbac, and undergraduate students and research assistants.

Because a postdoc is fundamentally a temporary trainee position, their activities should help prepare them for the roles and responsibilities they might find in a future academic or otherwise related position. Therefore, opportunities develop skills and experience in teaching, grant writing, consultation with industry, or other skills relevant for a particular postdocs career path are also essential.

Fundamental issues and challenges

The fundamental issue is that most postdoc positions seem to be set up to prepare postdocs to do one thing: conduct research in a major research institution (R1). Therefore, postdocs are prepared for temporary grant-supported i.e. "soft money" positions or for tenure track positions. There are not enough grants or TT positions to go around, so postdocs are basically being asked to "bet on themselves." The table stakes for this wager are quite large because postdoc salaries tend to be well below market rate for someone with a PhD. Postdocs are therefore expected to sacrifice considerable income for the chance at obtaining a future job in an incredibly competitive market. To do so, they are often expected to relocate for a short period of time with considerable uncertainty. This is particularly disruptive to postdocs with families. Finally, for postdocs who accept these conditions, their tenuous career prospects are often dependent on a single person, their PI, with very limited recourses should that relationship not be as supportive as they had been led to believe.

So in summary, the challenges are:

1) Limited career prospects in the field that the job prepares you for,
2) Low pay,
3) Need for temporary relocation,
4) Precarious dependence on a single benefactor without safeguards.

Existing NIH policies, programs, or resources

Increase minimum postdoc salaries. Increase grant funding to fund those salaries. Enable and encourage the prospect of remote work. Incentivize postdoctoral training that prepares postdocs for more diverse careers. Incentivize or require multiple mentorship models and/or institutional structures to decrease the dependence of postdocs on a single mentor.

Proven or promising external resources or approaches

Response 1424

Perspectives on the postdoc roles and responsibilities

To me, an academic postdoc is a position to diversify my scientific skill set while taking on increased leadership and mentorship roles for graduate students in that lab. The position is also a means to increase my marketability to future academic institutions, via the renown of my post-doc advisor.

Fundamental issues and challenges

(regarding recruitment and overall quality of life) Given my current time commitment to my graduate studies, my work-life balance is heavily slanted toward my work. I accept that. I worry about how much more time I would need to lead a successful post-doc position, and thus how much more decreased my quality of life may be as a post-doc. I view the increase in salary as a means to purchase means to offset some of that extra burden, but I seriously consider weighing the costs and rewards of the position.

Existing NIH policies, programs, or resources

I am aware of and have applied to fellowship opportunities through the NIH. I am also aware of some stipend increases for some research positions. I am however largely unaware of NIH programs and resources that could support my path toward a post-doc position.

Proven or promising external resources or approaches

No response

Response 1425

Perspectives on the postdoc roles and responsibilities

The postdoc to me seems like a screening process for faculty hiring where you have to prove that your PhD success wasn't a fluke. This isn't necessarily a good thing, and creates a pervasive feeling of constant evaluation. In my mind, a postdoc should be a place and time where you can expand your skills as a scientist for your own sake and the sake of better science, and not for the sole purpose of only then qualifying for a faculty position.

Fundamental issues and challenges

It wasn't until recently (last few decades) that postdocs became effectively required for academic positions in the life sciences. But people's lives are more or less the same (when you get married, have children, buy a house, etc). The prolonging of training is quite detrimental to the wellbeing of young scientists. Postdocs are severely underpaid, and have no bargaining power whatsoever in their employment, salary and benefits. The most basic issues have to do with these things, i.e. livelihood. It is an exploitative system based on cheap labor and infantilization in the name of justifying appallingly low salaries and meager benefits for incredibly well trained professionals. These sacrifices are not only for the postdoc tenure, but have long lasting repercussions. For example, people who do postdocs most likely just did a PhD during which they most likely had no retirement savings. A postdoc is for many the first opportunity to start saving for retirement and yet they can't because there are no employer benefits, or they can't because their salaries are so low they can't really contribute to a retirement fund. The most important period for retirement fund contributions is at the very beginning of one's professional life. Postdocs generally love science, but more and more we are asked to choose between science and our current and future livelihoods. Why is this necessary? Eventually, science will probably lose because people need to live.

Existing NIH policies, programs, or resources

The NIH pays its intramural postdocs more than the advertised salary minimums. But universities, no matter the cost of living of their area, continue to pay the minimum because they can. They will continue to do so until they are forced not to do so (either through collective bargaining, or NIH policies). The NIH should enforce cost of living adjustments to minimum salaries, rather than just suggesting them. The NIH should make sure that postdocs with different statuses are not treated unfairly (NIH award recipients are frequently treated as contractors and not employees and do not receive certain benefits!). And the NIH should require certain basic benefits including healthcare, childcare, retirement funds, etc.

Proven or promising external resources or approaches

Generally, better pay and benefits can do wonders for recruitment. Exhibit A: tech and pharma.

Response 1426

Perspectives on the postdoc roles and responsibilities

There are two answers. One is training to become a PI. The other is learning specialized techniques on the way to becoming a staff scientist or other non-independent role. The latter is clearly more common for most people, especially as the competition for PI slots fiercens. As such, there needs to be more and more emphasis on postdoc training that does NOT assume that the goal is "prep to write R01s", but instead to "do good rigorous science".

Fundamental issues and challenges

Cost, cost, cost. Grad students are older and more medically complex. So are postdocs. Gender identity and caregiver role has diversified. Amazingly, the further you diverge from being a single cishet white male, the harder it becomes to fit into the current model of "work hard for low pay in hopes of a long-term payoff".

And I say this as someone who IS a cishet white male. (No longer single, and my own parental responsibilities as a postdoc were a huge challenge.) It was hard for me. It would be impossible for many others. I survived only because of family wealth.

Until we acknowledge that postdocs need to be per se economically viable and only minimally uncomfortable, the pipeline will leak like crazy.

Existing NIH policies, programs, or resources

An easy one: index the NRSA/Kirchstein stipend scales to

a) living waves and

b) geographic wage variations.

I have now had two trainees in my lab actually turn down a T32 appointment (to my increased cost!) because they would have to take a pay and health insurance cut and they could not afford it because of family and medical circumstances. More generally, those stipends do not reflect what it costs to live in a major American city adjacent to an R1 institution, and until you fix that, we're going to lose the smartest people to industry jobs.

I will also say that I come at this as both a PI and a former postdoc. When I was trying to live on NRSA wages in Boston, it was almost impossible and my wife nearly left me simply because she was sick of being under financial strain constantly. (And I mean she had a lawyer and was threatening me with actual papers.) I see it now affecting the productivity of the people in my lab who need to be working.

Proven or promising external resources or approaches

Working environment: again, I am going to speak from many years of personal experience having been a postdoc. I had periods when I was on fellowship or NIH funded, during which my salary was less, I had worse health insurance (because I was now a "student" according to my university), and I got no retirement or other employee benefits. I had periods when I was paid directly from an R-series grant, and then I was an employee with full benefits.

This dual treatment needs to end. There should be one class of postdoc, treated as an employee of the grantee institution. Period. Institutions that refuse to do this simply should not receive any form of NRSA, K99, or other postdoc-oriented support.

Response 1427

Perspectives on the postdoc roles and responsibilities

The academic postdoc is a glorified scam promoting the illusion of research freedom for underpaid indentured servitude.

Fundamental issues and challenges

First and foremost: pay. Upon my PhD graduation, I had offers in postdoc academia and one in industry. The industry position paid 3.8x times the postdoc salary AND offered better, more concrete career progression. While I love academia and was excited about potential projects, how could the discrepant pay ever be a consideration? A secondary concern is obviously the struggle to attain professorships following postdocs. Ultimately it is a question of supply and demand, and I can't believe the NIH / universities are so naive to even be questioning why recruitment, retention and quality of life for postdocs is an issue.

Existing NIH policies, programs, or resources

Minimum pay?

Proven or promising external resources or approaches

No response

Response 1428

Perspectives on the postdoc roles and responsibilities

Postdoctoral scholars are obtaining advanced training and generating research outputs to make them competitive for permanent faculty/PI etc. positions. Although they are an asset to a lab, both for research productivity and builing infrastructure to train junior lab members, their primary goal should be to advance to the next step in their careers.

Fundamental issues and challenges

Salary and career prospects. Postdoctoral scholar are highly trained, doctorate-carrying experts. As is, they must choose between an uncertain postdoc-to-faculty/PI path that pays relatively little, does not guarantee a faculty/PI job, and likely requires frequent relocation, or a more certain professional path which likely pays more without frequent relocation. As faculty, I'd like to pay our postdocs more but salaries are dictated by what the NIH awards us to hire them.

Existing NIH policies, programs, or resources

Increase postdoc salaries. Provide more opportunities for senior postdocs to transition to faculty/PI positions, not only through K awards but also by allowing them to serve as co-PIs on grants with their supervisors to increase their salaries and funding success rates. This is especially important as many current postdocs have aged out of traditional F award mechanisms due to disruptions caused by COVID restrictions.

Proven or promising external resources or approaches

Increase postdoc salaries.

Response 1429

Perspectives on the postdoc roles and responsibilities

A successful academic postdoc is key to a successful career as an independent researcher. This is the beginning of your individual work and it is imperative that not only you have a supportive mentor but also the financial freedom to lead a project that isn't fully dependent on them. This is also the most difficult part of scientific training in my opinion.

Fundamental issues and challenges

Postdocs often have responsibilities outside of lab as at this stage of life they are starting or already have families to support, however they do not have the benefits of being a full employee (ie. parental and sick leave, holidays, annual raises). Often female researchers leave academia at this stage because if they do not have a partner that supports them or is supportive, then they have to find higher paying jobs in industry that also allow them time off. Male researchers at this stage also sacrifice time at home whether or not they are the primary earner in the family. Cost of childcare in this country is also prohibitive to many families so some researchers leave to even just stay home.

Existing NIH policies, programs, or resources

Fellowships can be awarded in a way that necessitates that universities count postdoctoral researchers as employees. The childcare grant is also helpful so expanding coverage and advertising it better helps, making sure universities are advertising it, etc.

Proven or promising external resources or approaches

Again, any sort of support that the NIH can provide in postdoctoral advocacy at private universities. Postdoctoral researchers often support the whole lab in addition to attempting to launch their careers. Even if there are supportive mentors there are still barriers since they are not full employees so they do not have the same university support for other aspects of life. Fewer and fewer postdocs operate as single-person, single-income, units.

Response 1430

Perspectives on the postdoc roles and responsibilities

You have a bunch of individuals who can’t afford to further any doctoral studies or research due to financial reasons.

Fundamental issues and challenges

You have a bunch of individuals who can’t afford to further any doctoral studies or research due to financial reasons.

Existing NIH policies, programs, or resources

More grants, more help financially to those who are interested in the work

Proven or promising external resources or approaches

More mentoring, more of a global perspectiveResponse 1426

Response 1431

Perspectives on the postdoc roles and responsibilities

It is like the equivalent of a medical residency but for a PhD looking to transition into an independent position. You are supposed to learn new skills but then rapidly apply those skills to demonstrate competency on the job market by publishing papers. Beyond learning to conduct research independently, you learn to manage others and make important decisions while having the “safety net” of a mentor. You learn to write grants and successfully funded grant proposals serve as a “ticket” out of the postdoc position. Other obligations include being one of the most senior personnel in the lab so you take a large load of direct mentoring, training, troubleshooting, sharing & developing protocols, and giving overall advice.

Fundamental issues and challenges

Lack of long-term stability in the position; Pay increases that are often nonexistent or lower than demonstrated competency; Skills becoming highly coveted by the mentor to the point that transitioning to independence is hindered

Existing NIH policies, programs, or resources

The K99/R00 pathway is an excellent opportunity. However, there should be rules on the degree to which a mentor can (or cannot) move into the research area of the postdoc’s K99/R00 proposal. There is a separation plan but in reality these lines get very blurred.

Proven or promising external resources or approaches

No response

Response 1432

Perspectives on the postdoc roles and responsibilities

I view the post doc as the opportunity to show yourself and the scientific community that you are able to independently initiate a project and take it from start to finish, acting with a high level of independence in deciding the trajectory of the project along the way. This view is more specific for postdocs planning to move on to academic or leadership positions after but I think it applies to most. I think other goals of the postdoc are to expand expertise, begin defining what your future area of science will be (academic), experience mentoring, and contributing to the overall productivity of the lab.

Fundamental issues and challenges

I think the biggest challenge to recruitment and retention is pay. Some grad students but most postdocs are now entering a phase of life where the discrepancy between their earning potential and the amount they actually make becomes too great to ignore, given the demands of their life (buying houses, having children, wanting to live in a way that is comparable to their non-postdoctoral peers). Other than that i

think there is a lot of inconsistency and lack of communication about the purpose of the postdoc and how much independence they'll be given during their time in the lab. This can lead to little sense of ownership over their science which, for me, is critical to enjoying and feeling invested in the work. Lastly, I have less experience with this, but there are other resources that postdocs are rarely offered that can be more accessible for their non-postdoc peers (for example, child care).

Existing NIH policies, programs, or resources

I think the NIH minimum salaries were a good idea, but should be increased. If we want to retain postdocs, i think this is the single most effective way to do that. Other resources, like childcare, would be helpful but ultimately are also issues of money/pay. I think issues of mentorship are harder to address at a policy level but better definition about the expectations for a postdoctoral position could help with that.

Proven or promising external resources or approaches

No response

Response 1433

Perspectives on the postdoc roles and responsibilities

Postdoc position to me is an opportunity to learn new methods that can help me shape my future goals and career. It's a great time to learn new methods, learn and train on grant and paper writings.

Fundamental issues and challenges

The main issue is financial. Postdoc salary is very low compared to other options. Especially here in the US, the cost of living is always on the rise and the postdoc salary did not increase to match that. I'm an international scholar, and I don't have many funding opportunities as well, so I think significant increase in the postdoc salary, and opening NIH funding opportunities to internationals can be huge step in attracting more postdocs

Existing NIH policies, programs, or resources

As I mentioned before, the main thing to me is opening the NIH funding opportunities that are available to US citizens to International scholars. Or alternatively having other programs that can support internationals

Proven or promising external resources or approaches

I would like to have a program that help with grant writing and in general scientific writing. Also, funded programs where postdocs can mentor Undergraduate or master students

Response 1434

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

I think there are 3 fundamental issues here.

1) Salary impacts quality of life and ability to raise a family, so raising the minimum salary would help retention.
2) Classifying Post-docs as full employees increases job security and mental health.
3) Providing child care and especially parental leave increases the likelihood of those who want families to do a post-doc.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1435

Perspectives on the postdoc roles and responsibilities

I view postdoctoral positions as necessary step towards becoming an independent Principal Investigator.

My experience is that Postdocs are viewed a paper generating machines. They have very little rights, especially if they are international and depend on PIs for working visas.

Fundamental issues and challenges

My experience is that Postdocs are viewed a paper generating machines. They don't have a lot of rights and there aren't many people or groups that advocate for them, especially if they are international. I have seen countless examples of Postdocs being exploited (working outrageous hours with very little pay) and they are forced to suffer through it because their work visas are dependent on the same PIs that are exploiting them.

Suffering through working as a Postdoc is not even worth the potential job prospects afterwards.

Existing NIH policies, programs, or resources

I think the NIH needs to work on changing the culture in science first and foremost. NIH policies are mainly responsible for the toxic scientific culture. Making it so difficult to obtain funding without really high impact papers and the amount of data required in a grant the NIH isnt even funding yet, creates incentives that leads to poor quality of life for both graduate students and Postdocs. The pressure that PIs feel trickle down to the people in their labs.

Secondly, PIs are not rewarded for great mentorship. They are rewarded for publications. There are many PIs that publish well, but in the process kill the passion graduate students (future postdocs) have for science. I dont know many graduate students in my program that are interested in pursuing science in the future and hence are not interested in applying for Postdoc positions.

Proven or promising external resources or approaches

No response

Response 1436

Perspectives on the postdoc roles and responsibilities

As a postdoc at a school of public health on a medical campus, I led manuscripts, developed data management work flows and built relationships with collaborators in support of an NIH-funded R01. The postdoc allowed me to continue conducting research on the disease system that was the focus of my PhD, and is a neglected area of research in the field. I saw the postdoc as a necessary step in developing my own independent research program in this area.

I was grateful to receive support from my supervisor to lead the submission of a grant proposal to a private foundation. Even with this support, because my salary was almost exclusively funded by the R01 grant, I struggled to set boundaries between my goals for developing independence and the needs of the grant.

Fundamental issues and challenges

Relocation. I likely would have found a non-academic job in the same city as my partner had my postdoc not been remote. My remote work arrangement allowed me to pursue the research that interested me without making substantial personal sacrifices (e.g., splitting time between my postdoc location and the city where my partner's job was while we were trying to start a family).

Paid parental leave. When I got pregnant, I quickly learned that postdocs fall through the cracks of parental leave policies on my campus. Because most postdocs are funded by the NIH in some way, the university didn't feel the need to extend the four-week parental leave benefit to postdocs, assuming that postdocs would be covered by the NIH's eight-week parental leave policy, which only applies to postdocs funded by NIH fellowships. Because I was by an R01, I had to cover my maternity leave with a combination of accrued sick and vacation leave and the short-term disability benefit I enrolled in in case I got pregnant. The fact that neither my campus nor the NIH extended paid parental leave to me really sent a message that postdocs are not valued for the contributions they make. I seriously considered alternative

career paths because of this, even though I was otherwise enjoying my postdoc experience. Even before our baby was born, staying in academia and having a family seemed like fundamentally incompatible undertakings. At the end of my pregnancy, I was offered and accepted a non-academic position that I expect will allow me to be both professionally and personally fulfilled (not to mention nearly doubles my postdoc salary). The biggest sacrifice in taking this position was giving up the neglected area of research that I am so passionate about.

Existing NIH policies, programs, or resources

Parental leave that covers postdocs on non-fellowship funding from NIH

Formal channels for recruiting remote postdocs for computer-based research

Paying postdocs competitively. NIH postdoc salaries can't even compete with similar roles in government, much less industry.

Providing guidelines for how to allocate effort for career development when funded on non-training grants

Proven or promising external resources or approaches

No response

Response 1437

Perspectives on the postdoc roles and responsibilities

I did three post-docs; two at the research bench and one in science education. the latter was, by far, the most influential for shaping how I share my work. There are many opportunities for post-docs to learn research skills, but far fewer dedicated to how we train new scientists, manage professional communication, and share our work beyond scientists. if you want to have greater impact and broader impacts, this is needed for diversifying our biomedical workforce.

Fundamental issues and challenges

Post-docs are often with a single faculty member who is intent on getting work published. While important, this misses the larger issue of shaping the career of the post-doc. Where do they learn a broader spectrum, the financial considerations of running a lab, and how to have difficult conversations so they aren't perpetuating inequities.

HIGHLY RECOMMEND HAVING POST-DOCS BE AVAILABLE TO JOIN EXISTING R25 GRANTS TO HELP MENTOR AND TRAIN YOUNGER STUDENTS —like SEPA, YES, and other similar programs.

Existing NIH policies, programs, or resources

Create funded opportunities within R25 and other training mechanisms for post-doctoral positions. Whether fully or in part, these experiences are unsurpassed for on-the-ground training of post-docs and help them recharge by seeing the light sparked in younger scientists in training.

Proven or promising external resources or approaches

Encourage near-peer mentoring teams within post-docs who work with younger trainees. highly influential. there should be encouragement of multi-level, interprofessional training for postdocs

HIGHLY RECOMMEND HAVING POST-DOCS BE AVAILABLE TO JOIN EXISTING R25 GRANTS TO HELP MENTOR AND TRAIN YOUNGER STUDENTS —like SEPA, YES, and other similar programs. These grants provide applied experience in mentorship, teaching, and sharing work. Plus, programs really need the support of diverse scientists —who often have to do volunteer with these opportunities. there are research opportunities and evaluative experience —it is not science education alone. This aspect is sorely lacking and we've found it to reinvigorate the science interests of our rising researchers across levels.

Response 1438

Perspectives on the postdoc roles and responsibilities

I run my own F32 grant and receive the rest of my funding (~25% RPE) providing methodological consultation for my PIs grant. I see my postdoc as a chance to transition to true independence by running my own grant primarily without oversight and running a team, while considering future career options

Fundamental issues and challenges

the pay is ridiculously small. I wouldn't be able to afford to live in a 1 bedroom in the cities either of my intuitions are in [redacted for anonymity] if my wife wasn't in finance

Existing NIH policies, programs, or resources

change to the postdoc minimum salary would help retain talent. Myself and many other methodologically focused researchers are fending off offers at least 2x the current minimum salary to do data science in industry, and more of us are taking this route. As a result, the people best positioned to steward public investments into rigorous research will leave the field.

Proven or promising external resources or approaches

This is an interesting question, but I don't know off the top of my head of any specific resources, but thanks for asking

Response 1439

Perspectives on the postdoc roles and responsibilities

When I was looking for my first postdoc position, I was encouraged to look for a lab where I could learn a new field. I was trained rigorously as a molecular neuroscientist and ended up joining a behavioral neuroscience lab. Although I had no issues understanding the work, there were issues at every turn with how I approached and completed my tasks. I had drafted a fellowship aims page that was mostly along the lines of the lab's expertise, with some molecular experiments I could add to bolster the findings. There was a specific quote that my former supervisor said that sticks out, "in writing your post—doctoral fellowship, we don't want to give the NIH the idea that we need anything from you; you are coming to us for training." In the end, I wasn't able to acquire the skills necessary to generate sufficient preliminary data and my contract was not renewed; the position lasted a year. It was a waste of time and frankly devastating. I am in my second post doc, and it is much more aligned with my prior training as a molecular biologist. I wish that more people would have encouraged me to just stick to my same field, because unless you have a supervisor that is patient and invested in your training, there is no point to doing a postdoc.

Fundamental issues and challenges

There is just no support for postdocs at all. there is no community building—offices of postdoctoral advancement are a great start. but overall, the structure of the appointment is a temporary position and discourages relationship building.

Existing NIH policies, programs, or resources

There are two long standing expectations of postdocs that make the postdoc quality of life untenable.

1. the "clocks"—one year post PhD for this grant, no more than three past PhD for that grant. All you are doing by imposing these arbitrary clocks is favoring applications from labs that already have a boat load of preliminary data. There is no emphasis on training for anyone that doesn't manage to snag one of these coveted awards.
2. moving from institution to institution. again, by imposing this policy and favoring people who are free to move, you have favoring single men. point blank. if you say you want to support postdocs as people you cannot in the same sentence tell us to move away from existing support networks every five years.

As an aside, the daycare stipend is a nice gesture, but realistically covers one month out of twelve in the state I live in.

Proven or promising external resources or approaches

Make our wages competitive. many of these quality of life issues can be overcome if our "maslow" hierarchal needs are satisfied.

Response 1440

Perspectives on the postdoc roles and responsibilities

Postdoctoral position for me means an opportunity to expand the knowledge acquired during the PhD and learn through practice how to independently develop a research project, gaining in leadership skills that will be required for the next step of becoming and independent researcher.

Fundamental issues and challenges

The main issue challenging both recruitment and retention in academic research is salary. The salaries in the US for a postdoctoral trainee are around a 50-60% of what a PhD could earn in the private sector. With those differences and the cost of living increasing there is no possible competition for academic research. That will be regarding national postdocs. Another major issue for international postdocs is the lack of rights as non-nationals. Meaning that your positions is always dependent on your PI, giving them either they are good or bad people a huge amount of leverage over these postdocs decisions and lives. Also the labor conditions (in some interviews some PIs explicitly say that in their lab you work 7 days a week) are not appealing even more considering the salary. If you put together all these issues with the recent experience of a pandemic, you could understand that conditions must clearly improve to become appealing to international people that are leaving their countries and families behind.

Existing NIH policies, programs, or resources

Better dissemination in order to reach the international candidates. I am an international postdoc and I am sure there are programs I could have applied to, but I haven't receive a clear information about their existence. Also some of them limit the applications to nationals, which is fine unless you are trying to increase the recruitment of internationals.

Proven or promising external resources or approaches

Different universities have started to increase their base salaries in order to attract postdoctoral researchers. Also facilitating applications to visas or the green card as well as access to tenure track positions in the faculties will be a great call for international postdocs.

Response 1441

Perspectives on the postdoc roles and responsibilities

I think that academic postdoctoral training is only valuable to those who want bolster their publication record and want to define their own research portfolio. If the idea is just to gain new skills, that is a part of any new role without being underpaid.

Fundamental issues and challenges

The biggest challenge to recruitment and retention is salary. Whether or not someone wants to stay in academia, postdoctoral years currently represent having all of the expertise to make real money, but choosing to be undervalued and overworked.

Existing NIH policies, programs, or resources

NIH pay scale

Proven or promising external resources or approaches

No response

Response 1442

Perspectives on the postdoc roles and responsibilities

Continued training to eventually be a PI. For me a postdoc is a really important time to learn and apply cutting edge research techniques. It is also important to me to diversify my training from the training I received in my grad lab. It's also important for me to have more independence in my work than I did in grad school. I expect a postdoc position to be one that has more responsibilities and a stronger leadership role in the lab. And also to expect a higher caliber of work from a postdoc.

Fundamental issues and challenges

The #1 biggest issue is salary. During grad school I was fine getting by with the bare minimum and not being able to save. But now I am entering into my 30s, I need financial security and I want to start a family. The low salary of the postdoc is very prohibitive of these needs. I really do enjoy my work and want to continue on in academia because I love my research and think it's important. However, by making barely more money than a student I am having to give up/push back the other adult goals in my life.

Existing NIH policies, programs, or resources

Please raise NIH minimum salary for postdocs.

Proven or promising external resources or approaches

Please raise NIH minimum salary for postdocs.

Response 1443

Perspectives on the postdoc roles and responsibilities

The post-doctoral experience that I expected to have was :

1) To be able to engage in research that expands my current skill set.
2) Develop expertise in a field of interest.
3) Have opportunities to apply and receive funding to pursue my own career as an independent research scientist.
4) Have the opportunity to engage in the latest technological advances.

Fundamental issues and challenges

Issues with recruitment:
1) Lower salary
2) Lack of career development guidance
3) Lack of support for international students with regards to visa
4) Lack of funding opportunities for international post-docs.

Issues with retention:
1) No security of career path.
2) Very few post-post doc opportunity
3) Lack of funding.
4) Low salaries

Overall quality of life:
1) Inability to have an average income and to be able to save for the future.
2) Better opportunities in industry
3) Lack of career development opportunities.
4) No support for international trainees with regards to visa.
5) Instability
6) Lack of forums for redressal of grievances.

Existing NIH policies, programs, or resources

MORE FUNDING FOR INTERNATIONAL POSTDOCS

MORE SALARY

VISA/IMMIGRATION SUPPORT!

Proven or promising external resources or approaches

No response

Response 1444

Perspectives on the postdoc roles and responsibilities

I see this the postdoctoral position as an opportunity to explore research with mentorship of an established researcher. This allows me to work as an apprentice in the academic field that I wish to do research in in the future, developing my network and solidifying my foundations in grants and scholarship.

Fundamental issues and challenges

Pay is the number one limitation of a postdoctoral traineeship. It is difficult to make a living with the low salary ranges provided by NIH grants. Recruitment was difficult because identifying a mentor who would provide support in my personal and professional development instead of being a "laborer" for an established academic was a rarity. Postdocotral positions are not setup for retention as they are short appointments with the hope of becoming junior faculty, which are positions that are diffcult to come by.

Existing NIH policies, programs, or resources

Funding related to postdoctoral fellowships needs to be increased for postdocs to be able to make a living wage.

Proven or promising external resources or approaches

No response

Response 1445

Perspectives on the postdoc roles and responsibilities

Propose and conduct an original research project that might be the basis for their lab once they have a faculty position. Mentor undergraduate or graduate students. Conduct service and DEI activities for their department.

Fundamental issues and challenges

The main limitation is the salary. Salaries and compensation is very limited and much lower than industry positions for filling similar roles. The limit on salary that is put by some institutions, anhd the difficulty of acquiring funding.

Existing NIH policies, programs, or resources

Increase the minimum postdoc stipend.

Proven or promising external resources or approaches

No response

Response 1446

Perspectives on the postdoc roles and responsibilities

The postdoc role is for individual seeking additional training that would help with pursuing a career in academia (albeit the training could also translate to a career in industry as well).

Fundamental issues and challenges

I believe the single most detrimental factor with postdoc recruitment/retention is the financial compensation/stability. Early career scientists are in a critical stage of their life. In order to be "successful" within a postdoc position, personal life decisions must be delayed or even abandoned. Generally, talented scientists understand their worth and are unwilling to make such sacrifices to pursue a career in academia.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1447

Perspectives on the postdoc roles and responsibilities

Exploitative training of little marginal utility in preparation for the faculty job

Fundamental issues and challenges

Poor compensation and prospects for a tenure-track faculty job despite intense work demands.

Typically long training time (4-8 years) post PhD before one can become competitive for faculty position appointments.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1448

Perspectives on the postdoc roles and responsibilities

Temporary training position to prepare the individual for a career in higher academia, administration, biotech startup, or upper level biotech positions. Responsibilities range from research, training/mentoring, teaching, management, and administrative work.

Fundamental issues and challenges

Cost of living crisis has reached a critical level, this is obvious from the many reports from high impact journals that lay out how severe this crisis has gotten. This issue is severely exacerbated by the recent increase in first-gen low income researchers that now hold a greater percentage of these positions (including myself). I am not a victim, the US biomedical research enterprise is the victim, brought on by its own set of outdated policies and embarrassing compensation rates (especially for high cost-of-living metropolitan areas, Boston, Manhattan, Bay Area, etc).

Existing NIH policies, programs, or resources

Stipend levels for 2023 are a joke and I'm actually embarrassed to be a postdoc at the "number one" school in the US. I don't know how much longer I will last with these "slave labor" stipends. I wish this was a unique perspective, but it is shared with greater than 90% of my colleagues.

Proven or promising external resources or approaches

HIGHER STIPENDS! If the NIH cannot fix this, labor unions will (labor union efforts are now underway at my institution). There are consequences for poor policies and poor management.

Response 1449

Perspectives on the postdoc roles and responsibilities

To me, my role as a postdoc, means that I am capable of contributing to the scientific knowledge and solve outstanding problems in the world independently. I take my years as a postdoc to gain further training in scientific methodology (problem identification, solution conceptualization and execution) to finally gain independence (open my own lab in a tenure track position). In summary, my work is to function somewhat independently to design, organize and conduct highly specialized and advanced experiments using established scientific protocols and procedures and in some cases designing new

protocols; summarize findings and publish results in research journals; assume general responsibility for scientific operations of the laboratory; provide supervision and guidance to junior technicians, students, and researchers.

Fundamental issues and challenges

1. Low salary. After 4 years of undergraduate, two years of masters and five years of PhD training in biological sciences, the salary, even at NIH pay scale, is minimal to survive. Even with the salary bump, considerable amount of my salary during postdoc is going towards health insurance. I get $2850/mo after taxes and insurance: $1480 (rent), Parking at work ($300), $100 (electricity), $100 Gas (or more during winter), Car payments 130, Phone and subscriptions: $100. That gives me $640 for everything else.
2. High intellectual demand yet low job security.
3. Over dependency on PI: Despite of hard work, the grad school/postdoc experience: whether you will publish, whether you will attend conferences and get networking opportunities, is dependent upon PIs. Ex. During graduate school, I was productive & had considerable amount of data in interesting directions. But my PI (indirectly) refused to publish until they got an R01. The R01s were submitted repeatedly from my year2-year5 just with the data that I had collected. I wanted to publish and graduate early, but it was impossible without getting R01. Therefore, form year3, my mental health, productivity and enthusiasm towards science deteriorated. My PI is still one of the better PIs. However, I was still unable to publish in time and even when I published it, 50% of my findings were retained for other grants and "future publications". It impacted my personal life. In Year4, my husband needed to move to another place due to personal reasons. As I was not allowed to publish and hence graduate, I remained. Our family had to suffer during COVID, which over-stretched our finances to credit-card loans & brought mental-health issues. I graduated after R01 was granted at the end of year5.

This is the story of a lot of hard working graduate-students and postdocs.

Existing NIH policies, programs, or resources

Salary could be increased.

Subsidized housing systems for postdocs would help.

Accountability for PIs in their actions.

Adding new grant mechanisms.

Proven or promising external resources or approaches

No response

Response 1450

Perspectives on the postdoc roles and responsibilities

Postdoc positions should deliver additional training for a scientist and allow them the opportunity to gain a deeper understanding of a subject and identify their own research niche.

Fundamental issues and challenges

- The pay is very poor and not competitive with salaries individuals with doctoral qualifications can obtain in industry.
- There is an expectation that postdocs should work very long hours, and accept a terrible work-life balance, for the prestige/freedom of being an academic.
- There is very much a sense that failure of a postdoc's research project is also a failure of the postdoc themselves. There is less of a 'team' mentality than in other positions.
- The pressure to publish and get grants is extremely stressful.
- There is very little support for families.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1451

Perspectives on the postdoc roles and responsibilities

I view my postdoctoral role as one of exploration. I have always regarded the postdoc phase as the time to establish an exciting research program and fall more in love with research. I consider the role as one to develop my writing, presentation skills, and research development. As a postdoc, I am responsible for training students and looking after the best interest of yourself the scientist, and the team surrounding you. It should not be a lone-wold situation.

Fundamental issues and challenges

The BIGGEST issues is financial. Most people, specially those without the resources cannot justify getting paid a salary that is not enough to maintain current inflation prices and housing/living costs. So primarily, without proper modification of NIH salary cap, this issue will never subside.

Existing NIH policies, programs, or resources

NIH Fellowships policies need to change. For a postdoc that was accepted on a T32, and then because of the climate, be expected to apply to more fellowships, it is not fair, nor does it make sense to apply for an F32 when it only funds for 1 year. The amount of work that it takes to put these grants together does not reflect the type of award you would get.

Proven or promising external resources or approaches

No response

Response 1452

Perspectives on the postdoc roles and responsibilities

A step above a PhD where you’re able to work on an independent project with more independence from the host PI/lab.

You’re expectes to bring new ideas and solutions to the table. The PI shouldn’t make conclusions for you.

Fundamental issues and challenges

Cost of living is high. There is lack of appreciation. Having a pizza party doesn’t make sacrificing time with your family feel better.

Becoming a full professor is challenging from a postdoc. not a lot of positions available.

As a postdoc, you’re told that you get paid less because it’s a training program. However, industry, you’re still learning on the job but get paid more with better benefits

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1453

Perspectives on the postdoc roles and responsibilities

contribute to the science community with a significant less pay and a uncertain future employment in the U.S.

Fundamental issues and challenges

How can a postdoc concentrate on their work when their future is uncertain next or couple of years later.

Existing NIH policies, programs, or resources

Make sure the program is equipped to keep burgeoning scholars in the U.S.

Proven or promising external resources or approaches

Given them some time and resources to grow.

Response 1454

Perspectives on the postdoc roles and responsibilities

As I see it, the purpose of the postdoctoral position is to provide early career investigators with resources and mentorship to launch their career in academia. This can be accomplished via structured didactics, individualized mentorship, facilitated communication with investigators working on projects similar to the trainee's chosen specialty, and provision of funds to receive specialized training.

Fundamental issues and challenges

The postdoc problem is likely nuanced, with complex, interconnected factors operating across multiple systems.

Recruitment—Postdoctoral fellowships suffer from a selection bias; most people who apply/know of postdoctoral positions already come from R1 universities or are 2nd generation PhD earners. Moreover, many graduate students who may be interested in a more academic career path, but come from less traditional/productive research programs may feel discouraged about their chances getting accepted into a quality postdoctoral position, let alone an academic career. This is exacerbated by those previously mentioned R1 candidates, who can afford to skip the postdoctoral process entirely and take a lucrative, non-public job thanks to their connections from their PI or family.

Retention: Due to difficulties in recruitment, there is a lack of diversity in academia, including postdoctoral fellows and mentors. Fellows from underrepresented or minoritized backgrounds may feel uncomfortable in these environments, and may be perceived and evaluated negatively due to the implicit bias of privileged others, which can lead to premature termination of postdoctoral fellowship. Furthermore, the stipends associated with postdoctoral fellowships are well below the expected income of someone who has earned a doctorate degree. As a result, the only people who can afford to take a postdoctoral fellowship are those with generational wealth, have no loans or significant personal expenses, or are financially supported by a spouse or family member. This further limits the pool of available applicants.

Existing NIH policies, programs, or resources

Consider expanding and continuing to support programs like NIH FIRST, which prioritize creating a sustainable, inclusive workforce in biomedical and behavioral research. Perhaps, this program could be expanded backward, created an NIH FIRST-type program that begins earlier in graduate training to create a sustainable pipeline for postdoc recruitment and beyond.

Proven or promising external resources or approaches

No greater investment could go farther than increasing the stipend for postdoctoral fellows. If postdoctoral fellows are supposed to be investments in the future of scientific research and the research enterprise, than why is the stipend less than what can be earned with a bachelor's degree? People are considering alternatives to postdocs (an academia as a whole) because the opportunity cost and hardship does not equate with the financial compensation considering alternatives and non-academic paths. A potential solution for increasing stipend might be to add a cost-of-living adjustment, similar to how base pay of VA jobs are supplemented.

Response 1455

Perspectives on the postdoc roles and responsibilities

A postdoctoral position in my point of view serves as dedicated time to develop new skills, hone a specific skillset, and provide additional time and training before becoming an independent research within an academic setting. As a graduate student in clinical psychology, there is an aspect of necessity in completing a postdoc position regardless of interest in obtaining an academic position afterwards as the majority of states now require postdoctoral training to be eligible for licensure. For some I believe the

postdoc can be seen as a hindrance after completing graduate school and the internship, or an increasingly long journey to employment which may not include research.

Fundamental issues and challenges

I believe a main challenge for postdoc researchers is the pay non commensurate with their earned degrees and the cost of living. Increasing pay for postdocs, providing protections (unions, HR) as would be common in other settings might help this as well. Increasing flexibility in working arrangements such as work from home and remote work could also aid in this as for clinical psychology students we typically have to move for internship and so moving just a year later for postdoc provides a burden both financially but also socially or for romantic/supportive relationships.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

Increased pay would be the most beneficial but clear standards for goals to achieve during the training, access to resources and improvement for PIs would help as well.

Response 1456

Perspectives on the postdoc roles and responsibilities

A time to receive more training but working more towards independence.

Fundamental issues and challenges

THE PAY. There is nothing alluring about earning $50K while individuals outside of academia can immediately begin earning six figures immediately after earning their PhD. On top of the terribly low pay, the hours are typically longer/less predictable than a non-academic job, which isn't really any issue that should change but something to be aware of.

Existing NIH policies, programs, or resources

Increase R01 budgets so PIs can adequately pay their trainees

Proven or promising external resources or approaches

No response

Response 1457

Perspectives on the postdoc roles and responsibilities

The Postdoctoral Position is a skilled trainee position. The two main responsibilities for a Postdoc are to perform experiments in the lab outlined in funded proposals and to train for future positions. The training can include many different aspects depending on future career aspirations, such as experiments, career development training, conference attendance, teaching, clinical observations, and internships at industry or government labs. The end goal of the Postdoc is to be able to comfortably lead independent research in a specific topic, generally at an academic, industry, or government institution.

Fundamental issues and challenges

The main challenges are financial stress and future/current job insecurity.

Existing NIH policies, programs, or resources

NIH policy on postdoctoral stipend could be adjusted based on location, potentially related to relative per diem rates for locations. Additionally, postdoctoral support should not have a time limit as current expectations for postdoctoral training are extended dramatically beyond previous expectations; postdocs who are competitive for tenure-track positions at R1 institutions require >5 years of experience. This has limited my own ability to apply for fellowship grants.

Proven or promising external resources or approaches

Successful Diversity, Equity, and Inclusion initiatives focus mainly on career development training. These initiatives would be helpful to incorporate into funding mechanisms to support Postdoc recruitment and retention. This would be an expansion of award supplements focused on diversity, without the specific requirement of a trainee from an underrepresented class.

Additionally, smaller funding awards, potentially directly from NIH Program Officers, to Postdocs to support independent investigations would be extremely helpful and inspiring. The all-or-nothing outcomes of NIH proposals, along with the extended time-frame for grant review, makes this process difficult for Postdoc funding. An intermediate funding allocation that supports experiments, potentially small pilot funding at the discretion of Program Officers with exciting but ultimately unfunded F/K awards, would be very helpful. This works well at Universities that give pilot awards for small research projects.

Response 1458

Perspectives on the postdoc roles and responsibilities

Post doctoral positions mean hardwork, under recognition and low pay to build research on something another senior investigator is passionate about because I "need" experience to even take an inch toward getting funding to do my own unique innovate research. I feel this is doing all the work only to leverage the reputation of another more established senior research because otherwise I will be given no consideration for large funding within NIH. In addition having the right network or knowing the right people also plays into the cost of being a postdoc and sometimes that is hard to do alone.

Fundamental issues and challenges

Pay is very poor and inability to be creative or do my own unique work. The long hours required because of the workload result in a poor quality of life.

Existing NIH policies, programs, or resources

K Awards are very helpful to allow mentored experiences. More such awards that allow a post doc mentorship, generous reimbursement and ability to be freely creative in research work and given adequate credit can help establish a pipeline. In addition streamlining applications to consider a "pitch" first to select promising work for a more robust application.

Proven or promising external resources or approaches

I do not know of proven external resources however a suggestion is to motivate institutions through funding mechanisms to invest in their current grad and early career investigators specifically rather than the default of looking for outside talent to bring in. It is disheartening to here the reality of loyalty to an institution is looked down upon because not "diverse" experience and to be encouraged to move to another institution when rich roots and collaborations may be well established at graduate institution. This loyalty can be viewed as a strength due to the relationships and connections already present and ready to be nurtured.

Response 1459

Perspectives on the postdoc roles and responsibilities

- major workforce in modern biomedical science
- have the skill level required to advance cutting edge research
- main 'think tank' of most labs
- major role in mentoring more junior scientists

Fundamental issues and challenges

No response

Existing NIH policies, programs, or resources

- Start treating the term of a 'postdoc' like a real job (it is!)
- Increase salary by at least 50% to match private sector
- increase salary of other more senior researchers accordingly
- Have more flexibility in retention of skilled postdocs
- increase benefits
- increase funding to junior PIs by limiting number of grants for senior PIs

Proven or promising external resources or approaches

Take a look at how well postdocs are treated in the private sector and then start making competitive offers. It's not rocket science.

Response 1460

Perspectives on the postdoc roles and responsibilities

A postdoc is a researcher, a scientist, training to become a professor. Meaning they already have the scientific and technical knowledge, and are "junior" researchers, learning how to train and mentor young technicians and grad students, learning how to submit grants, while conducting researcher under a "senior" researcher who is the PI.

Fundamental issues and challenges

Postdocs are currently viewed as students, when in reality they have already acquired the necessary knowledge and went to grad school and trained to become researchers. A postdoc should be considered as a junior researcher and not a student. Therefore, we shouldn't be considered as students and paid a salary that do not reflect our expertise and years of training. There isn't enough recognition of our status as researchers and this is also not reflected in the pay postdocs are currently receiving. I believe that these are the reasons why it is currently difficult to recruit and retain postdocs (I do not like to say "trainees")

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1461

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

Postdocs are extremely underpaid for their level of education, and for the amount of value they bring to academic science. I just finished graduate school, and transitioned to industry; my new salary is literally double what I would make as a postdoc. Also, in the more expensive parts of the country it is nearly impossible to provide for a family on a postdoc salary.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

You could pay postdocs more. This would be the most effective way to increase recruitment and job satisfaction.

Training, working environment, and mentoring all vary by lab and principle investigator. These variables are effectively out of your control, but postdoc pay is something you can fix.

Response 1462

Perspectives on the postdoc roles and responsibilities

As a grad student, I've heard a lot of my peers express hesitation about doing postdocs after finishing their PhD. There are a few reasons for this:

Uncertainty about the future: Postdocs are often short-term positions, typically lasting two to three years. After that, you're back on the job market and have to find another position. This uncertainty can be stressful and make it difficult to plan for the future, especially if you're looking to start a family or buy a house.

Limited career advancement: While postdocs can provide valuable training and research experience, they may not always lead to permanent academic positions or other jobs in the field. There's often a limited number of positions available, which can make it difficult to advance your career in the way you want.

Poor work-life balance: Many postdocs are expected to work long hours, including evenings and weekends, which can make it difficult to maintain a healthy work-life balance. This can be especially challenging if you have family obligations or other commitments outside of work.

Low pay: Postdocs are often paid less than other professionals with similar levels of education and experience. This can be a financial strain, especially if you have student loan debt or other expenses.

Fundamental issues and challenges

I think that statement is very relevant and important to consider. Postdocs are an essential part of the academic research workforce, but they often face challenges that can impact their recruitment, retention, and overall quality of life.

One of the biggest challenges is the lack of job security and career advancement opportunities for postdocs. Many postdocs work on short-term contracts, which can make it difficult to plan for the future and can lead to high levels of stress and uncertainty. Additionally, there are often limited opportunities for career advancement within academia, which can be frustrating for postdocs who want to continue pursuing research but don't see a clear path forward.

Another challenge for postdocs is the lack of support for work-life balance. Many postdocs work long hours, including evenings and weekends, which can make it difficult to maintain a healthy work-life balance. This can be especially challenging if postdocs have family obligations or other commitments outside of work.

Finally, postdocs are often paid less than other professionals with similar levels of education and experience. This can be a financial strain, especially if postdocs have student loan debt or other expenses.

Overall, I think it's important for academic institutions to address these issues in order to recruit and retain high-quality postdocs and support their success. This might involve offering more job security and career advancement opportunities, providing support for work-life balance, and ensuring that postdocs are compensated fairly for their work.

Existing NIH policies, programs, or resources

One area needed for improvement is providing more support for career development and advancement for postdocs. Many postdocs are unsure of their career goals or how to achieve them, and may not receive adequate support from their academic institutions. The NIH could provide additional funding or resources for career development workshops, mentorship programs, and other initiatives that help postdocs identify their career goals and take steps to achieve them.

The NIH could consider increasing the funding and support available for postdocs, especially in areas such as work-life balance and mental health. Postdocs often work long hours and face significant stress, which can negatively impact their quality of life and mental health. The NIH could provide additional funding or resources for initiatives that promote work-life balance, mental health, and other areas of postdoc well-being.

Overall, I think it's important for the NIH to continually evaluate their policies, programs, and resources to ensure that they are effectively supporting the postdoctoral training ecosystem and academic research career pathways.

Proven or promising external resources or approaches

No response

Response 1463

Perspectives on the postdoc roles and responsibilities

The postdoc for me is was a preparation for the next step. its giving me the sources to construct a competent cv. And a discover of what i am good and where i need to improve

Fundamental issues and challenges

The biggest challenge for retention is salary. I want to suggest 3 things,

1. higher salaries.
2. adjust the salary depending on the state (e.g. Texas, California) of the hiring.
3. "Postdoctoral Experience Level",

there are different levels depending on the years of experience that each university/professor uses under their own rules, for example I know several cases with more than 2 years of postdoc experience (on that site) and they still on level zero!! NIH have to find a solution in which the university/professor is obliged to raise you in level and salary for years of experience. And if he/she denies it, he/she has to give a good justification.

Existing NIH policies, programs, or resources

Postdoc are busy at the labs, we dont have time to check policies, salaries policies and everything. Help us by giving the resources easily. I know NIH has a lot of postdoc to handle, but help us to get treat well by taking care of our salary rise every year according to our years of experience

Proven or promising external resources or approaches

No response

Response 1464

Perspectives on the postdoc roles and responsibilities

I view it as a step above graduate school, you are still a trainee and it's still unclear if you are an employee of the institution or not. This brings with it a lot of uncertainly about benefits, job stability, and administrative issues. It's an important stepping stone, but in a way it still feels as though you are at the mercy of your institution and lab and could be exploited for free labor.

Fundamental issues and challenges

Having more structure to the position would help, as would requiring more from institutions on how to treat their postdocs. Setting hours and benefits would be extremely beneficial, right now these just can't compete with industry for interested scientists.

Existing NIH policies, programs, or resources

More specific postdoc training programs that come with explicit requirements for institutions to follow.

Proven or promising external resources or approaches

Not sure, my host institution has slowly started providing more support for postdocs. This includes postdoc symposiums, networking events, training opportunities, but is slow to implement structural change to really make a difference.

Response 1465

Perspectives on the postdoc roles and responsibilities

Postdoc positions allow for advanced training in project management, independent research, and mentoring. Postdocs have more potential for autonomy in their research projects and opportunities to take

on leadership/mentoring roles that are not offered to graduate students. They can work at a higher scientific level than grad students and progress projects faster. Despite these clear benefits to doing a postdoc fellowship, I know that postdocs are still chronically underpaid, do not have competitive benefits, and are dependent on their PI to be successful. There is still a large power dynamic between PI mentors and postdocs, and the relationships can be beneficial and positive or can be toxic and abusive. I view the drawbacks/risks of a postdoc fellowship as outweighing the potential benefits of advancing my training.

Fundamental issues and challenges

After 5+ years of training for a PhD while being underpaid, receiving little benefits, and potentially being abused in the academic training system, it is hard to justify prolonging the academic journey for grad students who want to have a career in industry or other non-academic careers. I am about to defend my PhD and know that I want to have a career in biopharma. 100% of the people I have done informational interviews with in industry have advised me to 'not waste my time' with an academic postdoc and instead join the biopharma industry at the PhD scientist level. They have all told me that academic postdoc training does not prepare scientists for industry careers (even those who did academic postdocs and are now in industry) and the postdoc training will not help your career advance faster in industry.

Also I think it important to address that as a female scientist, the pay gap, household/parenting responsibility imbalance, and biological clock all heavily incentives women to jump straight into industry positions. I can't afford to freeze my eggs on a postdoc salary but also can't afford to make big financial decisions such as buying a house or starting a family during my postdoc. Most postdocs I know who have made large financial/family planning decisions during their training have had significant financial support from their partners or extended family.

Also, I know many postdocs who are floundering—stuck in 6+ years of fellowship or at the instructor level without support from their PI to make progress on their project or advance to the next career move. They are still underpaid and overworked like grad students, and have less training oversight to ensure their success.

Existing NIH policies, programs, or resources

I think the academic training system is broken, and fundamental changes need to be made to make graduate training and postdoctoral training less burdensome in order to keep people in an academic career path.

We need to be paid SIGNIFICANTLY more, we need better health, dental, and vision insurance (we technically have it but most of us go into immense debt with 1 medical emergency), we need retirement benefits, we need mandatory sick time and vacation time, we need mental health benefits, we need accountability for abusive/toxic/inappropriate PIs/mentors/faculty/administrators, we need unions, we need a functioning human resources group for trainees, and we need opportunities for career development.

I keep hearing about 'the postdoc crisis' and academics complaining that no one wants to stick around in academia because industry pays better, but the draw to industry goes well beyond pay. There are systemic changes that need to happen in academia in order to keep trainees on an academic career path—don't just blame grad students/postdocs for being lazy and greedy for wanting to have a more promising work/life balance and fair compensation by joining industry instead. I think this survey is a good first step to hopefully begin to hear the experiences of trainees and try to make an institution that is supportive and willing to change for the better.

Proven or promising external resources or approaches

The NIH OITE has done a great job, but these resources are still not widely distributed to academic institutions that aren't NIH.

Response 1466

Perspectives on the postdoc roles and responsibilities

For me, my postdoctoral experience allowed me to gain expertise in a new methodology. This methodology was probably the main reason that I got a faculty position and stayed in academia. While this training was great for me, I struggled with matching the funding available through the NIH with my career stage. In addition, I sacrificed a lot personally to get this far in my career—moving away from my

family and friends for my postdoc and waiting to have kids until it was financially more feasible (as a faculty).

Fundamental issues and challenges

Financial: Many people now have significant research experience before even entering graduate school. Therefore, most people ready to start a postdoc are now more established (e.g. married, with kids). Therefore, finances are often limiting as child care and living in major cities is becoming more expensive. Moving to a new institute (often in another part of the country) is very financially stressful. Without a relocation stipend offered by my postdoc institute, I could not have done it.

Career outlook: Many postdocs feel hopeless—that it will be impossible to obtain a faculty position and that there is no point in doing a postdoc if not for a faculty position. I think many people would opt for a postdoc and be more likely to stick with it if there was a better chance that it would be worth it (either financially, by resulting in an academic position).

Parenting: As graduate students get older, postdocs do too. That makes it more likely that someone will want to start having kids during their postdoctoral training. In addition to the financial strain, it often feels impossible for people to consider balancing parenting with doing a competitive postdoc that can lead to a faculty position.

Existing NIH policies, programs, or resources

1) Allow PIs to ask for more money in their grants to pay postdocs more in high cost of living areas.
2) Expand administrative supplements for critical life events
3) Increase and expand childcare supplements ($2500 doesn't even cover one month of childcare for me)
4) Change the structure of postdoc funding. In my experience the K awards are only awarded after people are ready for a faculty position (often have already secured a position). F32s don't help as much for securing a faculty position. I think having an award early in the postdoc that can help secure transitional funding (like the HHMI Hanna Gray) i think would help with postdoc retention.

Proven or promising external resources or approaches

1) Transitional awards earlier in the postdoc to maintain promising trainees destined to be faculty (like HHMI Hanna Grey)
2) Programs that encourage shorter discreet postdoctoral training and increase the chance for a faculty positions like the Marie Curie programs in Europe

Response 1467

Perspectives on the postdoc roles and responsibilities

A postdoctoral position is an opportunity to add expertise and experience to one's readiness for an independent academic or industry position. Without a Ph.D advisor, postdocs have more independence and work in self-guided, self-censored ways. They also get involved more heavily in the what it takes the run a lab, not just to run the sciences, as they are supervising the work with trainees with less experience.

Fundamental issues and challenges

The insecurity of a faculty position at the end of many years of postdoc is a considerable deterrent. Outgrowing a postdoc of 2-5 years and remaining in the same lab comes with serious personal costs. The postdoc is seasoned and competent but not in charge of the research, not able to compete for funds, and often under pressure to leave.

Existing NIH policies, programs, or resources

I don't think the situation would be improved by NIH policies, programs, and resources. The core of the problems boils down to demand and supply; are we training more postdocs than what academia can absorb? Probably, yes. Are we training more graduate students that academia can absorb? Definitely yes. Is it necessary for the Ph.D. to go through postdoctoral training to take a teaching position, or other science-related but not research-centered positions? No.

Proven or promising external resources or approaches

A broader national conversation on this topic is warranted. The desire to improve the postdoctoral experience both for the postdoc and the PI has be considered within the realistic framework of funding, competition, job shortage, career uncertainty, and the likelihood that the investment of often more than a decade into academic research does not pay dividends.

Response 1468

Perspectives on the postdoc roles and responsibilities

First time research position post-graduate program. Can perform research with minimal PI input. More administrative and logistical responsibilities than a graduate student (budgeting, grant application, experiment design, procedural design, overseeing students, etc), but with PI understanding that the post-doc is new to these responsibilities and is finding their way, may need advice, and may make some mistakes. Still significant hands-on role in laboratory and field work in addition to these added managerial responsibilities.

Fundamental issues and challenges

Work-life balance. Post-doc positions are typically sought during prime reproductive years for educated women. Often families feel if they do not begin their families at this point (or earlier) their opportunity to have children may pass. In addition to the long hours and intensity of expectations for postdocs day-to-day, there is also an expectation that post-docs will move to whatever city/state they are hired. This is incompatible with romantic relationships unless the partner has no ties and complete freedom of movement. It is also incompatible with children who require consistency for their developmental health, and who begin school, make friends, and have family ties of their own.

Existing NIH policies, programs, or resources

Women are more likely to experience a career gap in response to starting a family than men. Minorities are more likely to experience family-related career gaps than white individuals, due to cultural values surrounding family. Originally men were doctors and scientists, and their wives took care of their children while they pursued their careers unhindered by those distracting responsibilities. We are still bumbling about trying to figure out what to do with the children now that both men and women pursue careers. Because young children need parents, the solution is not to stop women from having a gap. Instead, provide a path to re-entry after a gap. This will allow talented women who decided to spend time with their children to re-enter their careers, and it will also encourage more men to incur a gap of their own, with the assurance that there will still be a career waiting for them though they enjoyed some time focused on fathering. Leveling the playing field in this way will enhance diversity of skillsets on research teams by enhancing racial and gender diversity on those teams. A route to reentry might mean accepting a certain amount of re-training in post-doc positions, or it might mean creating a new position for those with a research gap, that pays a little less than a post doc, expects more than a graduate student but less than a post doc, and that funnels directly into a post-doc.

Proven or promising external resources or approaches

Creating an environment that supports people in their wish to have families. Not everyone wants a family, but realistically most people do. And they want to raise their children well. Especially educated people, who understand a great deal about child development and have high expectations for their child’s learning, mental health, and performance. These people will often find that no one can support their infant or toddler the way they can, and it feels inadequate to pick up the toddler from a subpar caretaker at 6pm just to put them to bed. If you cannot find a way to support EARLY parenting and research simultaneously, you will lose people. If you do not allow them a route to re-entry, you will lose them for good.

Response 1469

Perspectives on the postdoc roles and responsibilities

It is a training position to learn responsible, rigorous and reproducible experimental design and research that can be applied towards human health.

Fundamental issues and challenges

Stipends/Fellowships i.e. pay is so limited that you can only sustain yourself and pay off loans, not enough for a regular life. Retention is not possible because it is made clear that you have to find a job in 5 years or less but projects and resources offered do not make this timeline possible. The entire process is much harder as an international fellow

Existing NIH policies, programs, or resources

Workplace environment and culture needs to change and this means the grant funding agency aka NIH must survey the labs receiving funding for honest feedback without coercion from the PIs or advisors.

Proven or promising external resources or approaches

NIH's own OITE resources are very helpful and can be implemented from the graduate school stage. While this is helpful it isn't enough

Response 1470

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

The salaries inhibit recruitment of diverse candidates, particularly those from low-income backgrounds (i.e., first-generation college graduates). As with most PhDs, those from economically disadvantaged backgrounds have already assumed thousands in costs for their education, foregone salary/etc in lieu of higher education, and their next step (postdoctoral fellowship) only offers compensation that is ~50% of what they could make in the field. However, NIH must remember that candidates from low-income backgrounds are (likely) the most educated person in their family. And that prospective candidate has (by far) the greatest earning potential of any member of their family (who, remember, are struggling economically). The current compensation structure for pre-/postdoctoral fellows is the largest impediment to recruiting a diverse workforce. In reality, we cannot simultaneously:

1. recruit a diverse workforce; and
2. offer recruits drastically below-market compensation.

Those are in direct contradiction of each other.

Existing NIH policies, programs, or resources

Response 1471

Perspectives on the postdoc roles and responsibilities

As a postdoc, you report to a PI but are expected to lead most of the experiments on your own with minimal input or guidance from your PI. You are also expected to train other people in the lab including lab techs, graduate students, undergrads etc. You are expected to publish papers in high impact journals, write grants, attend conferences, build networks, and stay up to date with the field.

Fundamental issues and challenges

1) Low pay: Academia offers MUCH lower pay as compared to industry which makes it impossible to stay in academia especially with the current inflation.
2) No protection of rights: Unlike industry, academia provides zero protection to post docs/graduate students in case they are getting abused/exploited by their boss/PI.
3) No work life balance: As a post doc, you are expected to put in 50-60 hours/week and most post docs usually have a family that they want to spend time with.
4) Maternity leave: As a woman, I cannot imagine staying in academia and have kids. The maternity leave is almost nothing as compared to what the industry offers.
5) Always worrying about grants: As a post doc and aspiring PI, you always have to write grants and get funding. Highly stressful.

Existing NIH policies, programs, or resources

Increase pay: It should be somewhat closer to what the industry pays.

Protecting the rights of graduate students and post docs.

More maternity and paternity leave for post docs and graduate students.

Better work life balance.

Showing some empathy and concern for employee mental health

Proven or promising external resources or approaches

No response

Response 1472

Perspectives on the postdoc roles and responsibilities

Fundamental issues and challenges

3 fundamental issues: pay, benefits, and respect. All three are severely lacking for graduate student work, and still lacking for a post-doc position. Even if you are willing to put up with these things, the odds are still low that you will secure a faculty position after completing a post-doc.

Pay and benefits are far too low for people around child-bearing age. There is also this pervasive sentiment among the PIs that graduate students and post-docs should be grateful for whatever scraps the university is giving. This has been demonstrated very clearly with the recent strikes across US universities. The message to graduate students is clear, 'we don't value you, get back to lab.' I don't know a single person in my cohort who is willing to do a post-doc in the wake of how the faculty treated students during the strike.

As someone who worked in industry prior to pursuing a PhD, the treatment towards students and post-docs is appalling. It would never happen in private industry because people would be able to quit or move teams without taking a hit to their career prospects. The real irony of this is, many PIs think they are good mentors. They have never had to deal with the consequences of abusing their trainees, because there are NO consequences. In fact, I would argue they are rewarded for overworking and abusing their workers.

I am 3 years into a 5-year grad school program. If this was a job I would have quit 3 months ago after the strike. At this point, I'm too invested to leave without the PhD, so I will stay. I'm sure once I graduate my boss will boast that he did such a great job mentoring me. Nothing could be further from the truth.

Existing NIH policies, programs, or resources

The NIH could increase the wages for graduate students and post-docs while also stipulating minimum benefits. Benefits like parental leave, sick days, and 15 days of vacation per year guaranteed to the workers.

The NIH also needs to rethink how principal investigators are trained. PIs become PIs because they are good at science, THATS IT. It does not mean they have good interpersonal skills. Why does the training

stop once PIs reach this stage? In industry, my supervisors had to attend management workshops twice a year.

Additionally, I had to review my supervisor with their supervisor yearly. This review helped identify problem areas and determine which kind of management workshop my supervisor should attend. It should go without saying that these reviews were confidential. I really think this approach could encourage better leadership.

Finally, graduate students and post-docs should have a dedicated HR to help them navigate these things and track incidences within the university between trainees and faculty. Why are these metrics not being tracked and reported?

Proven or promising external resources or approaches

Brene Brown, Simon Sinek, and Adam Grant are people who come to mind as experts in the workplace satisfaction field.

Response 1473

Perspectives on the postdoc roles and responsibilities

Generating independent hypothesis and testing them more independently than other lab members; assisting with training of lab members; having their own funding

Fundamental issues and challenges

European post docs pay more than US post docs. Congress has the ability to raise the post doc salary, but doesn't. PhDs have no business making 60k a year, these r people who quite literally waste their 20's in effort to advance science and help the world. This salary is causing almost all graduate students from my school and program to stop going for an academic route. No one wants to do a post doc for 60k$ when an industry position pays $150k+. We can't be expected to start families during these positions with such poor pay for people with PhDs. Post doctoral work is hard, and should be paid appropriately. At least closer to the level of a junior faculty member, because let's be real that's what they act like half the time. If you don't solve this, US post doc positions will be only filled by foreign scientists. Not to mention it's an Equity and Diversity issue to pay people so poorly.

Existing NIH policies, programs, or resources

Spend resources lobbying congress to increase cap on post doc salaries thru NIH funding.

Proven or promising external resources or approaches

It's all the money, guys. We give up years of our life for this training: by the time we have a PhD we deserve to make more than 60k$. This also doesn't change for folks working in cities with higher costs of living.

Response 1474

Perspectives on the postdoc roles and responsibilities

The postdoctoral position is an additional training period after the PhD but it's also the implementation of an advanced skill set and education we have gained during graduate studies. In doing so, we are professionals and are treated as replaceable individuals in the academic infrastructure.

Fundamental issues and challenges

In reference to my previous comment, the biggest issues I face with my postdoctoral position like many are the low compensation and lack of benefits. This makes my education and training feel not valued and looking forward to leave academia.

Existing NIH policies, programs, or resources

Salaries and stipends could dramatically be improved to start.

Proven or promising external resources or approaches

Attention to the nature surveys on postdoctoral satisfaction, quality of life and mental health.

Response 1475

Perspectives on the postdoc roles and responsibilities

I worked as postdoc researcher for 4 good years with aim of becoming an independent researcher, who could write grants, mentor young researcher and create a valuable research setup. Postdoc stage to me is supposed to me a training ground for all these goals with the idea of getting enough exposure and mentoring in general.

Fundamental issues and challenges

- high uncertainty in funding situation. My postdoc was always 1 year and then was renewed which gave me a constant feeling of instability to carry out my research.
- very low remuneration as compared to my industry peers. Leading to poor living conditions.
- lack of support for grant writing, and mentorship for academic track.

Existing NIH policies, programs, or resources

- salary should be increased specially for universities in big cities like Boston.
- Atleast 2 years support for postdoc positions
- A systematic postdoc support system for making pathways in academia

Proven or promising external resources or approaches

No response

Response 1476

Perspectives on the postdoc roles and responsibilities

I see it as research time for myself and personal development because the salary is not enough for my qualifications and administration are often rude & colleagues can be awful to one another because of the competition.

Fundamental issues and challenges

Postdocs are experts and I find it incredibly insulting to be spoken to as a trainee with over ten years of experience writing algorithms for public use. The salary isn't livable, my partner left me for someone else because he said I didn't earn enough money. I'm 36, I will never own a home, I will never find a partner or have children because I wanted to use my talents to help people. I'm viewed like garbage by most people in society because of my salary, despite paying approximately $160000 to landlords to rent their property over the last ten years of being shunted around different institutions for research projects.

Existing NIH policies, programs, or resources

Improve the salary and understand how qualified and expert post docs are.

Proven or promising external resources or approaches

None

Response 1477

Perspectives on the postdoc roles and responsibilities

Prepare trainees for independent scientist job, including managing a group of people, establishing research projects and acquiring financial support

Fundamental issues and challenges

As a postdoc in Boston, the living cost is rising to the point that our salary can minimally keep up with our minimal life expenses. I would imagine it is much more difficult for postdocs with kids and family. I am currently working in a lab that provides great training for me scientifically, but in general the effort from

postdoc and pay level received as a postdoc is very poor, especially compared to similar level positions in industry.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1478

Perspectives on the postdoc roles and responsibilities

A postdoctoral position offers the opportunity to diversify my skillset, gain experience applying to grants, and gain additional mentoring on mentoring students. A postdoctoral position can also serve to build a foundation of research upon which to base a tenure package if the topic area is independent of that of the supervising Professor and if the researcher owns/retains the intellectual property rights.

Fundamental issues and challenges

I never saw NIH funding as an open door to begin with. I had a class on writing NIH proposals in graduate school. My advisor wrote in the handbook that she expected us to apply for NIH doctoral training funding. Differing stories are circulating about whether students can get funding from the NIH when in a lab without NIH funding. Further, the number of people getting NIH funding is pretty small and limited to those with direct experience in labs funded by the NIH. At an R1 minority serving institution, I never heard of the NIH. I didn't know I needed that network for grad school. I didn't find a way to access it for a postdoc. The family pressure not to pursue one based on the low salary didn't help. The lack of reference letters from my own PhD committee and the lack of mentoring support during and following the pandemic did not help. Having my PhD advisor leave the university made it really hard to finish the PhD to begin with. The memories of faculty behaving inappropriately and the universal fear that I won't be able to find a healthy work environment regardless of what sector I go into are not helping me figure out the next steps in my career.

Existing NIH policies, programs, or resources

I have no experience with which to answer this question.

Proven or promising external resources or approaches

I wish you the best of luck improving things.

Response 1479

Perspectives on the postdoc roles and responsibilities

The postdoc in theory should be a brief apprenticeship to gain new skills before going on the academic job market. In practice, the postdoc has become a prolonged period in which highly skilled individuals are exploited as cheap labor to support the academic research system.

Fundamental issues and challenges

As a postdoc I felt expendable. I was acutely aware that only ~20% of PhD trained individuals end up on the traditional academic track with the majority finding positions in industry. During my training I also considered going on the industry job market and participated in resume building activities to make myself more competitive in the private sector. Completing a postdoc is not a valuable asset when transitioning to industry and merely delays the number of years that you have high earning potential. Increasing the NRSA pay scale is very appreciated and the shift several years ago that made universities start using the NRSA minimum pay for postdocs is a move in the correct direction. However, there is nothing to require or incentivize universities or individual departments/Chairs to follow the NRSA pay scale based on years of experience. So on top of low pay (relative to industry) it is really salt in the wound to postdocs who are not funded (or are not eligible) for fellowships to be paid less than their postdoctoral peers despite having the same or more years of experience. Finally, I think there has been a growing awareness of how challenging (read: hopeless) it is (particularly at smaller R1 institutions) to successfully compete for NIH

research grants. When my mentor submitted a fellowship application in the early 90s the funding rate was 50%. Meanwhile the funding rates have dropped while the pool of hopeful graduates has increased. The ESI and New Investigator initiatives (and RFAs like the Katz R01, DP2, Trailblazer R21, etc.) are much appreciated, but I think it will take time to determine whether these programs are successful and then further time to communicate that there is any sense of "hope" to individuals coming along the training pipeline.

Existing NIH policies, programs, or resources

I benefited from T32, TL1, and K99 funding as a postdoc and I attribute my retention in academia in large part to these funding/training opportunities. The specific training grants I was a part of were unique in that they had very structured mentoring from the training grant (or RFA) organizers with regular group meetings and workshops. Similar to graduate school, this created a sense of a 'training cohort' in which you had several postdocs at similar stages of training meeting regularly, setting timelines, and making deadlines (e.g., career award submissions). This created a sense of camaraderie, community, and repository of shared knowledge that is often lacking when a singular postdoc is hired in a new city/institution. I also do not think I would have made it to where I am now if I had children as a postdoc. The expectations about productivity and the stresses of long work days and lack of departmental support (my institution only revised their postdoctoral leave policy in 2019 to have 8 weeks paid leave) make me suspect that I likely would have left for a higher paying job with more benefits and more work-life balance. The grant supplements to support life events are a great resource for those on F or K awards and more NIH support along those lines (e.g., supplements to R awards to support trainees not funded by NRSA awards to go on leave?) might offset some of the negative perceptions about having family while in a training position.

Proven or promising external resources or approaches

No response

Response 1480

Perspectives on the postdoc roles and responsibilities

During my time as a graduate student, I have interacted with quite a few postdocs. From my experience, the role of the postdoc can be summarized as follows: They are typically responsible for supervising and overseeing their own project (or multiple projects) in the lab. As a part of this, they are often required to directly mentor junior scientists. At times, they can have more mentoring responsibilities than the PI of the lab, which they need to balance with performing experiments.

Fundamental issues and challenges

In academia, this topic is discussed quite a bit. Why does there seem to be less postdocs? In my experience, I think it really comes down to the amount they are paid and the amount of hours they are required to work. They are often required to work significantly more hours than graduate students but only get paid marginally more. In addition, in the current economy, it is difficult to support a family (wife+kids) on the average postdoc salary. Typically, the spouse of the postdoc needs a job as well. This requires the use of childcare, which is insanely expensive. Overall, these difficulties encourage students to go into other fields, which can pay significantly more.

Existing NIH policies, programs, or resources

Honestly I don't know what improvements can be made. The NIH is trying hard to address some of the issues I stated above. Providing childcare funds to those with fellowships is a huge step. However, it is simply not enough. Ultimately, postdocs need to be paid more and, in that regard, I believe the NIH's hands are tied.

Proven or promising external resources or approaches

I have nothing to say here.

Response 1481

Perspectives on the postdoc roles and responsibilities

Stopgap between a PhD and PI position. Useful to further one's training, but should not be used to create "super postdocs".

Fundamental issues and challenges

Salary. Industry pays 2-3x more than academia/government, so market forces push applicants to more lucrative career options with better work life balance. The fix is straightforward—a dramatic increase in salary (NIH levels) and at least 4 weeks of annual leave, like in Europe.

Existing NIH policies, programs, or resources

Annual leave policy should be updated to allow for more leave.

Proven or promising external resources or approaches

Some institutions in the EU are closed after 6pm and on weekends. Maybe this is something to look into it improvements in the working environment are needed. Also—salary.

Response 1482

Perspectives on the postdoc roles and responsibilities

Post-doctoral position means to me as stage where I get build my career to become a principal investigation. A Post-doctoral position is where Junior researcher are independent enough to define the lines of research for the future careers.

Fundamental issues and challenges

Because there are more PhD graduates than faculty academic positions, there is fierce competition and most post-docs will never be accepted in tenure track positions. Also, PhD students and post docs sometimes are seen as cheap labor so they don't get the guidance needed and that is why institutions graduate more PhD than academia needs. Most Post-doc positions don't pay well for the requirements, expectations **and responsibilities** that accompany those positions and therefore many post docs go to the industry. Academic environment has become very toxic not appropriate for mental well being. I found stunning that we were publishing on mental health and we were not expected to sleep or have personal life while on graduate school. Is specially difficult for women to think about family and a career in academia due to the lack of support for pregnancy, child delivery and child care.

Existing NIH policies, programs, or resources

Regulations about the working expectations for a post-doc position and an increase in salary.

Support trainees when they start families. Provide equal pay and equitable laboratory start-up funds for women. Rethink the tenure clock. Institutions should establish or expand reliable, high-quality, and on-campus childcare for children of both trainees and faculty.

Proven or promising external resources or approaches

No response

Response 1483

Perspectives on the postdoc roles and responsibilities

To begin independent research under the supervision of a postdoctoral mentor. This is a specialized job that should result in guidance for innovative studies that can be continued in the postdoc' own lab as a future PI. This is a JOB not a training position.

Fundamental issues and challenges

Funding is a major issue, as academic postdoc entry salary is 1/2 to 1/3 of an industry salary. There is a huge variability in benefits based on university/institution. For adults who have spent 9-10+ years studying for their degree, a starting salary that is barely above the living wage is insulting.

Prior to graduate school I had a job with a salary of $50,000/year. It is a waste of my time to spend 5+ years on a degree that will result in a postdoc salary that it $55,000/year.

Existing NIH policies, programs, or resources

More opportunities for non citizens

Proven or promising external resources or approaches

No response

Response 1484

Perspectives on the postdoc roles and responsibilities

The postdoctoral position should be a chance to continue training and developing more scientific independence, learn new skills, and contribute to a field of study. It should be time limited with clear goals that work toward a longer-term career for the trainee.

Fundamental issues and challenges

Unfortunately, this is frequently not the case. The postdoc experience seems to vary greatly on the whims of the mentor/PI. Unlike a medical residency, fellowship, or even PhD program, the postdoc feels very unregulated. The mentor and the trainee often have opposing motivations. The mentor would love the exceptionally cheap and highly skilled labor while the trainee would like a paper, grant, and/or a real career paying a real salary. There often seems to be little interest in the future of the postdoc beyond the big paper the lab wants to publish or the grant the PI needs for the next 4 years.

Existing NIH policies, programs, or resources

Shared success. What percentage of a lab's postdocs have moved on after 3-5 years to run their own lab or an industry position? If the lab isn't supporting their workforce development then they should be losing points on their grant proposals. You need broad structural and cultural changes to create a better postdoc experience. Your best way of doing this is with money.

Proven or promising external resources or approaches

Create comprehensive postdoc programs with a beginning, end as well as some external oversight that isn't solely within domain of PI. There might be something to learn from the bigger industry postdoc programs who support the overall development of their postdocs.

Response 1485

Perspectives on the postdoc roles and responsibilities

To my understanding, an academic postdoc is a necessity for pursuing a career in academia (and maybe multiple postdocs). It is a way to expand your skills and independence as a researcher to answer niche questions and think critically like a PI would. The research may be more high risk and reward than a project that a graduate student may take on. Postdocs are also senior members of the lab who can give advice and guidance to younger/more junior lab members.

Fundamental issues and challenges

In my opinion, pursuing an academic postdoctoral position is not something particularly interesting to me. To an extent, it seems to be a continuation of the poor work-life balance that graduate students experience. Furthermore, the pay in academia (especially as a postdoc) does not seem to be a fair compensation for someone who has gone to great lengths to obtain a terminal degree like a Ph.D. The combination of these factors (along with the arduous path to establishing an academic career) makes a postdoc seem very unappealing, especially when jobs in other sectors (such as industry) may have a better work-life balance/financial compensation.

Existing NIH policies, programs, or resources

One key step to promoting academic pathways and a healthy work environment for postdocs is to increase funding. This may come in the form of major grants awarded to the PI or more trainee benefits. Although there are grants and fellowships available in academia at every level, the base rate of the award or the

salary cap at the university makes it extremely difficult to live comfortably, especially when (as mentioned previously) the compensation does not reflect the amount of work that the individual has gone to obtain their qualifications.

Proven or promising external resources or approaches

No response

Response 1486

Perspectives on the postdoc roles and responsibilities

I view my postdoc job as the means for my self to contribute to science and public health protection. I also view it as an important transition in my career life as my postdoc experience directs me towards where I want to be, which can be very different than when I just started the postdoc job.

Fundamental issues and challenges

Low payment. I love research work, I love academia, but I could not afford a kid's daycare fee in [redacted for anonymity] as a postdoc. The low living standard I have with a PhD degree makes me rethink if the choice of being a postdoc in academia is correct.

Existing NIH policies, programs, or resources

Increase the NIH salary standards for postdocs, please.

Proven or promising external resources or approaches

University of California system and University of Washington have increased the lowest salary for postdocs at $65,000/yr. Postdocs need to be realized, for our hard, nonstop work yet only with this poor payment.

Response 1487

Perspectives on the postdoc roles and responsibilities

As a relatively "successful" postdoc who obtained an Assistant Professor position at a top institute, I view postdoctoral training as an important training process for scientists who are determined to pursue an academic position. However, the postdoctoral career in the US is so tough that I think it is almost not sustainable. As a junior investigator, I am also about to transition to an industrial PI position, so I can tell the pros and cons of each side. I am so happy to leave academia with no reservations.

Fundamental issues and challenges

Low pay, poor health insurance, almost no retirement benefit, almost no respect for personal time, and a high failure rate. Postdoc has no life. There is a clock counting down when you start the position. If you cannot manage to publish well within five years, your life, I mean your entire life, is doomed. Only 1% of postdocs can get a decent professorship. Most of the other not-so-lucky ones need to figure out what to do afterward. Compared to PhDs who go to the industry right after graduation, postdoc fellows have 0 advantages, their academic working experience is not considered, and they have to start as year 0 when they find a different job—the postdoc experience worth almost nothing. For the lucky ones who eventually become PIs, the salary is about 50% less than the PIs in the industry, with very few benefits. The US academic system is taking advantage of the "immigration restrains" to force foreign postdocs to stay in these much-underpaid positions, which drives out talents who deserve better. Postdocs have already invested their time (5-8) years to obtain a Ph.D degree (again, another underpaid position), when they finish, they have almost no rewards for life if they choose to continue the postdoc route.

Existing NIH policies, programs, or resources

Standard NIH R01 should at least double or triple to meet the inflation of costs on everything. Otherwise, the entire research community will get worse and worse.

Proven or promising external resources or approaches

Cut the supply. We don't need these many postdocs and these many graduate students for biomedical research when only a tiny fraction of them can be successful.

Response 1488

Perspectives on the postdoc roles and responsibilities

Before joining my graduate program, Postdoctoral positions meant that there is a clear path to establishing a career path in academia as a tenured professor. Since joining graduate school and learning more about the stifling process and unhealthy competitive patterns in academia with a subpar salary for work done or years put into the development of these expertise skills, postdoctoral positions seem like a less enticing career option.

Fundamental issues and challenges

The lack of certainty as it concerns obtaining a tenured position in college after years of hard work. The crippling selection process with lack of diversity and the minor salary range that does not match up, or at least compete with the salary gap in the industries or with professors

Existing NIH policies, programs, or resources

Create more avenues for diverse applications for grants for early researchers, making it accessible to both international and national graduate students.

Proven or promising external resources or approaches

No response

Response 1489

Perspectives on the postdoc roles and responsibilities

A training period to learn life skills as well as new, cutting-edge technologies of the field, while being part of a research project.

Fundamental issues and challenges

Funding issues for projects, lower incomes and benefits compared to industry jobs for the same experience levels.

Existing NIH policies, programs, or resources

Better training programs/workshops for developing various skills (communicating, tools, etc.) held more routinely, funding/stipends based on the living costs of the specific place, better mentorship/communication tools to help new appointees take advantage of the available options.

Proven or promising external resources or approaches

No response

Response 1490

Perspectives on the postdoc roles and responsibilities

The postdoc position represents a transition from trainee to trained. It is the first step to becoming an independent scientist.

Fundamental issues and challenges

The salary in academia is TOO low! If you take into account the hard work and the number of years spent on studying why should you choose to stay in academia when the industry out there would be paying you 3 times more?

Existing NIH policies, programs, or resources

Improving the salary. This is the main reason why it is so difficult to find a postdoc. After the covid pandemic, very few people move from Europe to come to the US. China has put even more restrictions on students that want to start a career in the US. And everyone here knows that American citizens don’t pursue an academic career because of the salary

Proven or promising external resources or approaches

It is not a matter of ecosystem. It is a matter of money and work-life balance

Proven or promising external resources or approaches

No response

Response 1492

Perspectives on the postdoc roles and responsibilities

As I progressed through my graduate education I struggled with the question of whether I wanted to pursue my initial dream of becoming a faculty member and having a lab of my own where I can train the next generation of scientists in the field that I love and the ability for me to have financial security and the opportunity to live a life outside of the lab. At its conclusion, I chose to leave academic science for a myriad of reasons, but the top three being that I saw no opportunity for career progression as a post doc, I saw it as another opportunity to subject myself to the inherently broken and abusive environment that is cultivated at top-level academic institutions, but most of all I saw there was no way for me to compete with established professors for access to funding which would ultimately mean my life post graduation would be insecure for the next 10 to 20 years or until I made tenure/full-professor.

Fundamental issues and challenges

The fundamental problem for post doctoral scholars is the treatment of being a Ph.D. but making a salary that is a fraction of other professions like tech. There is also no incentive to stay in academia because faculty only hire to fulfill their grant obligations with no thought to provide skill training and further education opportunities to their trainees for their career advancement. While I was a grad student I saw too many times how post docs in our lab and others were not allowed to attend conferences, workshops, or obtain other training to advance their own goals. PI's have the unilateral authority to restrict what they worked on and even would create hostile work environments to force work at break-neck paces. Post doctoral scholars are the backbone of academic research, especially for larger labs as they are the ones on the front lines doing the training and teaching of graduate students and interns. Another challenge I think exists for post docs is that PI's take advantage of scholars who are on Visas. Many post docs from foreign nations come to the U.S. to train in the best labs we have to offer but end up in situations where they feel backed into a corner because they are on a visa, and this forces them to be subjected to inhumane working conditions. While this may not be an issue the NIH can solve directly, I think working with policy makers to create safeguards that allow post docs to move labs or institutions to protect themselves is necessary.

Existing NIH policies, programs, or resources

As i did not stay in academia beyond my graduate education, I don't really know much about the NIH's policies for facilitating post doctoral career advancement but some of my general ideas are as follows. Create training grants that enable post doctoral scholars to obtain skills training beyond the lab such as people and resource management training. I think such a program would be highly beneficial to academia holistically because many PI's lack fundamental people and resource management skills and this is a root cause some of the issues with PI's today. As mentioned above, work to create policies for post docs on Visas so that they are protected from bad actors like abusive PI's. Increase the salary minimum for post docs to be competitive and adjust for inflation and cost of living. In many institutions, post doc salaries do not increase annually to adjust for rising costs. This is detrimental to the mental health of post docs and

the science as a whole. Many institutions do not give graduate students or post docs guaranteed PTO, and even if it is mentioned in their handbooks the PI has 100% discretion. This policy needs to change because many academic scholars suffer from burn out due to the working conditions which also hurts the researchers and the science. I think holistically, the NIH must enforce proper training of new faculty, with continued training on skills for being effective managers. In many labs, especially at top tier institutions, labs are like individual dictatorships which stifles creativity, discussion and innovation, which is the life's blood of this enterprise. Creating an environment in academia that encourages discussion and creativity rather than compliance is necessary.

Proven or promising external resources or approaches

I think a model to look at is the post doctoral environment in Europe. While it is not perfect, my colleagues overseas have better work life balance, happiness and are still able to pursue their lives outside the lab in fulfilling ways.

Response 1493

Perspectives on the postdoc roles and responsibilities

To me, postdoctoral position means opportunity to continue research and grow as a scientist, learn and prepare for further role as a professor and principal investigator leading independent and innovative research. As a postdoc, I expect to be rewarded for years invested in education that always required personal sacrifices. As researchers with PhDs and many years of practical experience, we are experts in our fields and we show outstanding knowledge. At work, we are expected to show high quality of research, innovative and significant findings while maintaining scientific integrity. Additionally, we are being asked to do this fast to ensure our 'competition' will not reach the goal before we do. In another words, we are being pressured and since it is our career and future, we are pushing ourselves to the limits, working extra hours and often 7 days a week.

Fundamental issues and challenges

Postdocs in most groups are being treated as technicians that supposed to produce data quickly. There is lack of respect to postdoctoral fellows and years they spent on actively working and learning. The status 'trainee' is highly discouraging. In many European countries, you need to complete Master course before applying for PhD. This means approx. 10 years of higher education/working in Academia, and being just few years apart from advancing to Professor, yet we are being called 'trainees' with low salary and little benefits. It is shocking and sad to understand how little PhD and being Postdoc means in this country.

Postdocs contracts are not protected from sudden termination, which often happens when PI decides that postdoc=trainee is not productive enough (how do you reliably measure productivity in research?). There is poor support and clarity for international personnel—currently issues related to taxes are overwhelming and stressful to majority of my colleagues, and despite seeking help to understand U.S. tax law and forms, we have no support from the institution. Low basic salary and no annual raises are another issue that highlight lack of respect to this position.

Existing NIH policies, programs, or resources

I don't have sufficient knowledge on available NIH programs to address this question.

Proven or promising external resources or approaches

If possible, NIH could try to establish and enforce general law by which Postdocs will be protected and treated with deserved respect. Currently, these BASIC issues are not right in any Academic institution, and only local Unions are trying to improve working environments, but this still, affects our productivity and wellbeing. Considering many public complaints, it is obvious what are the issues related to postdoctoral working ecosystem. The solutions are very simple and relate only to primary rights and fair contracts, the only question is if anyone care enough to change it?

Response 1495

Perspectives on the postdoc roles and responsibilities

The postdoctoral program for me was like an introduction into the world of research as practiced in the USA. I was expecting it to be more like an independent research but that's not entirely true. On some occasions I still feel like a graduate student. I just feel that the postdocs are overburdened with work especially if they are very serious and committed to their job. Like the more you work the more work they give you. You cannot expect to finish a project fast and take some rest.

Also, I got this strong feeling of the postdoctoral workforce being treated as cheap labors. At low salary, most faculty hire too many postdoctoral students only to push the lab work.

Fundamental issues and challenges

The biggest challenge is surviving in a new country with such low salaries. Postdoctoral students mostly aim to become academic professionals and delivering high quality research is a key towards that goal. However, while we spend 8-10 hrs of our prime working age every day in lab, the salaries are less than half when compared to our friends in other fields of work. I came to USA to pursue science not to waste time thinking how will I manage my expenses on a tiny salary.

Second thing which really gets me thinking is the sheer discrimination between graduate students and postdoctoral students. I have faced it myself on certain occasions. Like it feels they are given a lot of flexibility and choices at every stage but postdocs are treated as cheap labors.

The issue with visa situation is another reason for students from particular countries feeling unwelcome to pursue postdoc here. We either have to get a waiver that takes almost a year since Covid happened or continue to be without green cards for so long and that becomes a limiting factor in getting recruited.

I also feel most institutions really on hierarchy and known connections or big names while recruiting. As such majority of people with good research ideas and backgrounds but no connections here in the USA get ignored. It's very rare that you hear a new recruit not being from a handful of the top institutions.

Existing NIH policies, programs, or resources

NIH has been working towards salary raise and that's a good starting point. However, the gap is huge and especially for students in big cities the NIH scale has not been sufficient. Better salaries culminate in better quality of life and mental wellbeing. So that is something which needs to be actively worked upon.

Most institutions do not have an active postdoctoral quality of life committee that works seriously. Considering postdoctoral students are mostly immigrants I feel they should be allowed to be an active part of institutional clubs and groups. This way people feel much more welcome and that is a good networking experience as well.

Also, if NIH could help solve or atleast make the visa crisis better. Most postdoctoral students pay a huge sum of their salary on taxes but they are not able to reap the benefits of that because of their visa status. I think solving the salary and immigrant's crisis is of utmost importance if we want to maintain a healthy and secure working environment & attract more postdoctoral students to the institutions here.

Proven or promising external resources or approaches

Response 1496

Perspectives on the postdoc roles and responsibilities

The bridge from graduate school to independence.

Fundamental issues and challenges

The salary is really low!

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1497

Perspectives on the postdoc roles and responsibilities

I view the postdoctoral position as a time-limited position to be used for career development and additional training. However, I do not view myself as a student anymore. Thus, I also want my position to have benefits, reasonable vacation time, good salary, etc. I view it as a time to explore new subject matter areas or gain additional career development tools such as teaching/mentoring experience, while being able to produce high quality data for the lab.

Fundamental issues and challenges

The single largest challenge for postdocs is insufficient salary. Many of the other problems post-docs face (inability to afford childcare, housing, debt, etc) would be addressed by salary increases. Retention of postdocs would also be improved by increased salary.

Existing NIH policies, programs, or resources

Increased training grant opportunities would be the most important for promoting academic research careers.

Proven or promising external resources or approaches

No response

Response 1498

Perspectives on the postdoc roles and responsibilities

Simply put, they are essential personnel who work on each funded project and generate scientific data.

Fundamental issues and challenges

We were able to recruit good international postdocs from China and Korea (until five years ago) who have been key for our research. However, for many reasons (e.g., many top institutions in those countries can hold top postdocs by paying more, publishing top papers, establishing strong networking, etc.), the applicant numbers are markedly decreased in recent years.

Existing NIH policies, programs, or resources

The nih salary stipend is too low and we are unable to supplement based on regional cost of living with nih funds.

Existing NIH policies, programs, or resources

Stipend vacation family leave

Proven or promising external resources or approaches

Online training for postdocs, requirements for mentorship training for mentors, require nih funded mentors to submit idps and postdoc submit yearly progress report to nih. This may prevent exploitation

Response 1500

Perspectives on the postdoc roles and responsibilities

Goal is to gain additional skills, papers and expertise (admin and research) for running an independent lab.

Postdocs bring experience, maturity, perspective to new lab where they can engage in an intensive research period to generate publications. They are still trainees in the new area but transitioning to independence. Should take leadership position in the group and thereby gain skills in mentorship and management.

Fundamental issues and challenges

Highly competitive academic job market means postdocs are very long (5+ years). Pay should be higher.

NIH needs to increase stipend levels as this is the guideline used by PIs and departments.

Modular budget should be increased to account for this change, or allocate supplements for postdoc pay increases.

Existing NIH policies, programs, or resources

https://grants.nih.gov/grants/guide/notice-files/NOT-OD-23-076.html

Excellent step in the right direction but this money need to come from somewhere—administrative supplements?

Proven or promising external resources or approaches

No response

Response 1501

Perspectives on the postdoc roles and responsibilities

Academic postdocs must contribute to rigorous evaluations of the impact of their tools on improving patient outcomes. They must be encouraged to publish papers in top medical journals describing the impact on outcomes based on their pragmatic randomized controlled trials.

Fundamental issues and challenges

The main problem is that postdoctoral training programs are not teaching the modern skills needed to perform the job upon graduation. Instead they are taught how to perform weak evaluations and continue the hype and hand waving.

Existing NIH policies, programs, or resources

NIH often has a policy that forbids randomization. This forces postdocs and others to perform weak science. The NIH should have a policy that no one is every forbidden from using randomization in their research.

Proven or promising external resources or approaches

You asked for a "Proven or promising external resources or approaches that could inform NIH's efforts to enhance the postdoctoral training ecosystem."

There is an excellent new book that would be ideal for helping postdocs learn the skills they need. The title is:

"Artificial Intelligence for Improved Patient Outcomes—Principles for Moving Forward with Rigorous Science" by Daniel Byrne.

https://www.amazon.com/dp/1975197933/

Postdocs would learn how to conduct pragmatic randomized controlled trials for their research projects.

The issues of retention and burnout are related to the frustration with weak science and lack of forward progress. Postdocs must be taught how to build and validate robust predictive models in a modern way. Currently their training in this area is lightweight and lacks scientific rigor. For example few can explain regression to the mean or intention-to-treat. They need to be taught the pros and cons of machine learning methods but also logistic regression so that they can use the right tool for the right problem.

Response 1502

Perspectives on the postdoc roles and responsibilities

The postdoctoral fellow should be placed in a position to learn new skills and gain competencies that enable them to establish and lead their own laboratory. The learning of these skills is expected to involve hands on leadership of research projects. Often postdoctoral fellows are learning skills sets that they were not able to learn during graduate school (a graduate advisor can't teach someone everything).

Fundamental issues and challenges

The postdoctoral fellow is a trainee position. They should be able to see how the postdoctoral experience is a step in the career path. If there is insufficient career options in paths that come from a postdoc, the fellow will not find the work satisfying. The postdoctoral experience should be viewed similar to medical residency or serving as a law clerk.

Most NIH investigators have been trained to see the postdoctoral fellow as a workhorse in the laboratory. They hire only people who already have the skills needed for the project and don't really teach those people new skills. Career progression is viewed as continuing their existing line of investigation. If the postdoctoral fellow is a trainee, not an employee, the scientific work they do should instead be a vehicle for learning and establishing new ways of thinking and approaching problem and gaining skill sets and experiences that were not available as graduate students.

Existing NIH policies, programs, or resources

If the NIH really cares about postdoctoral fellows they would enforce a 3-4 year limit on the postdoctoral experience. Why should a postdoctoral fellowship be ilonger than medical school?. The NIH already implies something like this with the time limits on K99 applications. This will force investigators and institutions to have technicians and staff scientists rather than "trainees" as the primary workforce, not trainees.

Proven or promising external resources or approaches

There you go again saying "job satisfaction". Instead we should be talking about "educational satisfaction"

Response 1503

Perspectives on the postdoc roles and responsibilities

Sometimes it can be difficult to more on from post doc positions into something more permanent, especially when trying to pursue a career in academic research.

Fundamental issues and challenges

Academic institutions are competing against biotech/pharma companies, matching salaries and benefits is very challenging.

Existing NIH policies, programs, or resources

NRSA T32 stipends could be increased and training programs could provide more interactions with biotech/pharma companies as a bridge so that trainees can succeed.

Proven or promising external resources or approaches

No response

Response 1504

Perspectives on the postdoc roles and responsibilities

These individuals play an important role in all biomedical research and should be considered important partners with the PI not non-key personnel.

Fundamental issues and challenges

At many institutions postdoctoral trainees are considered "temporary" and thus not vested into retirement programs or other important benefits programs. This is detrimental to their future careers. Broad policies are needed to be sure this is corrected. Also pay increases are needed and should be standardized. The NIH payscale is a good start but still far too low. Research institutions and departments need to invest in professional development programs.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

Response 1505

Perspectives on the postdoc roles and responsibilities

As the PI of a training grant in biomedical informatics, we have found it more and more difficult to recruit postdoctoral candidates. Although potential candidates often say they see the value of the type of mentored training offered by a high-quality postdoc position, the stipend we can offer through the training grant is a fraction of what they could earn in industry or junior faculty positions. (Our field is growing rapidly enough that many PhD graduates can get hired directly as junior faculty.) Without far, far higher stipends, much closer to what an entry-level faculty job offers, candidates recognize that they would be foolish to take a postdoc. Please consider raising the stipend we can offer through NIH training grants.

Fundamental issues and challenges

Increase stipends

Existing NIH policies, programs, or resources

Increase stipends

Proven or promising external resources or approaches

Increase stipends

Response 1506

Perspectives on the postdoc roles and responsibilities

it is a huge opportunity and one that i am grateful for. i love the autonomy i get, all while learning new things. it is a lot of responsibility and of course i want to get paid more. everyone does. but i can always leave and get paid more elsewhere—this is why people leave.

Fundamental issues and challenges

we are required to attend too many pointless meetings/trainings, we get too much departmental spam email, and diversity is shoved down our throats constantly (when it is obvious many of the higher ups do not actually care about diversity as much as covering their own tails or pushing their own agendas)

Existing NIH policies, programs, or resources

funding for INDIVIDUAL awards (f, k, etc) should not be so explicitly tied to the mentor having several R01s. these awards should be longer and not so temporally constrained.

R, U, etc grant amounts should be reduced and given hard limits. and PIs should be limited in the amount of NIH money they can receive so that more people can be funded. people do not need as much money as they put in their (completely made up) budget—everyone knows this is a joke, so why bother bean-counting and having reviewers/accountants waste their time looking at budgets they do not know anything about? just cap it. constrain the budget that way—PIs can then run their lab accordingly. we have an understanding of what our research costs. if we know our budget is 250k per grant per year max, we can plan accordingly.

Proven or promising external resources or approaches

the only things that will make a difference are salaries and job security, or some combination of the two. without familial financial support nobody wants to do a postdoc when they get paid $60k and yearly contracts that are dependent on their PI's grant succeeding in a study section filled with bonehead reviewers whose decisions amount to a coin toss.

Response 1507

Perspectives on the postdoc roles and responsibilities

The postdoctoral position should provide time, mentorship, and access to resources for the postdoc fellow to start building their independent program of research. The postdoctoral fellow should not be viewed as an advanced research assistant or spend most of their time supporting the work of someone else.

Fundamental issues and challenges

Postdoctoral pay is very low, which is an issue that is more severe in high-cost areas (e.g., Boston, New York City). The postdoctoral position also does not come with research funds, typically.

Existing NIH policies, programs, or resources

NIH-funded postdoctoral fellowships would be improved if the salary floor was raised significantly if fellows received at least some funds to conduct a pilot project (e.g., $15,000+) in addition to the funds provided for conference presentations and courses, if there was an organized mentorship program outside the host institution to make certain aspects of mentorship and support equitable. For example, a summer institute where fellows received feedback and support on a grant application, etc.

Similar to Ph.D. positions, there also needs to be a balance between postdoctoral positions and the availability of faculty positions. People spend years in postdoc positions aiming for a faculty position, and it is very hard to achieve even with postdoc training. Indeed, it seems that the more postdoc training one has, the chance of receiving a tenure-track faculty position declines.

Proven or promising external resources or approaches

No response

Response 1508

Perspectives on the postdoc roles and responsibilities

A postdoctoral position is a key valuable academic research position. A postdoc has sufficient training to take on advanced responsibilities in conducting and designing experiments, as well as management roles and directing lab output (writing grants, papers, etc.). It's a full time job, not a "trainee". Postdocs should be seen as an important invaluable resource in how academic labs operates. They have undergone significant training to get to their position and should be valued and full time employees.

Fundamental issues and challenges

Pay. The salaries for academic postdocs are abysmal and practically no benefits are given. In 5-10 years no rational American citizen obtaining a PhD is going to remain in academic science. You cannot pay up to half of what an equivalent position would pay in industry and expect people to pursue an academic postdoc. The system is deliberately designed to devalue the labor of postdocs so PIs and Universities can exploit them for their training and expertise, keeping them trapped in a "transitional" state and underpaying them deliberately. It is an absolute travesty that is harming US science output and productivity. Working hours are high, stress is high, expectations of responsibilities are on par with positions that would pay up to double the salary at a government or industry job, and benefits (health care, child care, retirement etc.) are nearly nonexistant. How the NIH thinks this is sustainable for people who are at the middle of their productive lives/careers while simultaneously increasing the time (4-7 years) it takes to move on to the next career stage is laughable.

Existing NIH policies, programs, or resources

Increase minimum salaries for postdocs.

Proven or promising external resources or approaches

Increase minimum salaries and benefits.

Response 1509

Perspectives on the postdoc roles and responsibilities

An academic postdoc can fulfill multiple purposes depending on one's goals. The "PI tenure track" postdoc purpose is to prepare one for becoming an academic PI including establishing a distinct scientific focus and research program as well as the leadership capabilities to run a lab. "Alternative track" academic postdocs purposes include wanting to gain particular experience (technique or field) that will allow them to transition to a non-PI position such as a staff scientist in academia or industry. There is currently no distinction for these types of postdocs, this should change. "PI tenure track" position by nature tend to be longer (5-6 years) because it takes time to get high impact publications and establish oneself in a field to the extent required to get a PI position, and also require a RO1 level type of project. "Alternative track" academic postdocs could be shorter (2-3 year MAX) and on smaller projects with the primary goal of additional training/experience for a person and to help the PI move smaller projects forward or get preliminary data etc with discrete, timely deliverables. The support for these positions could and should look different! I believe establishing these distinct types or "tracks" of postdocs would help postdocs find positions that match their goals and help PI's get the right people on the right projects and career trajectories.

Fundamental issues and challenges

I chose an industry postdoc over an academic postdoc for several reasons. First, I knew I did not want to be pursue being a PI because the dismal chances of landing an academic PI position. I think I could enjoy being a PI, but the odds are not in anyone's favor. Second, the industry postdoc gives me the chance to work on academic-like projects with a higher salary (~92,000 a year base pay, plus bonus), a competitive retirement package, established vacation days, good healthcare, fringe benefits (gym membership etc.), and is only three years maximum. Ultimately, I could not put my life on hold for an academic postdoc. My wife and I may want to have children soon, I couldn't rationalize trying to support a family on an academic postdoc salary when I could get a higher paying position elsewhere. I also have aging parents that may need support both financially and with my time.

Existing NIH policies, programs, or resources

1) Expand existing programs like the F99/K00 and make the pay more competitive (increase 62 K/year to 82 K/ year) and offer retirement packages.
2) Require PI's to provide retirement packages for postdocs. The impact here could be huge. This factor alone is a huge deterrence for many people considering a postdoc. I can not think of a single other position that requires a higher education degree that does not offer a retirement package.
3) As hinted at above, promote the idea of PI's distinguishing between "tenure track" and "alternative track" postdocs. I think this would help pair people (PI's and postdocs) better as well as pair goals and projects better. NIH could also create funding opportunities that PI's apply for based on these positions.

Proven or promising external resources or approaches

1) Competitive pay
2) Retirement packages
3) Goals and training alignment

Response 1510

Perspectives on the postdoc roles and responsibilities

Overall, a postdoc is a very appealing position. An opportunity to do interesting research under the mentorship of an experienced faculty member.

Fundamental issues and challenges

The problem with postdoc recruitment and retention is not quality of life or opportunities but extreme uncertainty about the future. Medical doctors do residencies and fellowships for low pay because they are nearly guaranteed a stable, highly paid and highly respected career after training. Meanwhile academic graduate students and postdocs are bombarded with statistics about how few of them find junior faculty positions, how hard it is to obtain grant funding, and how few of them achieve tenure. Additionally, postdoc positions narrow ones specialization which limits their job prospects. As such, many postdocs opt for higher paying industry jobs as soon as an opportunity becomes available. More and more graduate students are being hired directly into junior faculty positions and that has become more of the expectation, making postdocs even less appealing.

Existing NIH policies, programs, or resources

The NIH should promote policies that either increase the pay of postdocs or decrease the uncertainty of future opportunities in academia. Postdocs need to paid at a rate competitive with industry. Keep in mind, new PhDs in industry jobs get "mentorship" from senior scientists, growth, and training and opportunities, so the mentorship in an academic environment is not as much of a draw for a postdoc anymore. To decrease uncertainty about future job prospects, the NIH could increase the number of K99/R00s funded to increase the acceptance rate. Ideally, that mechanism would not be limited by funding constraints so that any quality application can be funded. The NIH could also promote "pathway to faculty postdocs" for institutions to guarantee a faculty position with startup funding after certain milestones are met during a postdoc.

Proven or promising external resources or approaches

It is no secret that immigrants make up a large portion of postdocs who are willing to take on the low pay and career uncertainty of a postdoc. Policies to ease immigration would solve the challenges with postdoc recruitment. Getting US Citizens to do postdocs will require a much larger investment from the NIH.

Response 1511

Perspectives on the postdoc roles and responsibilities

My postdoc has entirely been focused on research with some mentoring of graduate students. That is mostly how I envision a postdoc, to be focused on developing a complementary set of skills to those gained in graduate work so that you can start off in a new direction from either of your advisors. I have

enjoyed the mentorship aspect of it, but I feel like in large labs (>10 people), the postdocs tend to do most if not all of the technical advising while the PI focuses on continuing to write grants to fund such a large group.

Fundamental issues and challenges

The salary issue is huge. My university does a great job topping off NIH funding, providing subsidized childcare, excellent health insurance, etc. But, the cost of living for many of the best institutions is still ridiculously high and rent takes up half of my stipend, even with it being topped off. NIH minimum salary should be cost of living adjusted for each institution.

There is also a growing expectation that training time for postdocs should be 5 or more years. This has caused fundamental conflict in working on interdisciplinary projects since in engineering, shorter postdocs of 2-3 years are the norm. So when going on the job market after 2 years of postdoc, my biomedical mentor was less than enthusiastic. Training times are stretching on and on. For women in particular, this is very bad if it causes them to delay having kids, as there are increasing health risks with age.

Existing NIH policies, programs, or resources

A very simple thing could be to make the K01 renewable indefinitely to create a straightforward funding mechanism for soft-money staff scientists. There could also be a K01B or somethings that provides increased research funding and smaller salary support (with total $ to the university being greater than the K01) to encourage institutions to fund those positions internally, permanently.

Create more funding mechanisms like the NIBIB Trailblazer award with an intermediate level of funding that prioritize young investigators.

Change the K99/R00 mechanism to not require 1 year at the postdoc institution and extend the eligibility to faculty in the first 2-3 years of their independent position, provided they have appropriate mentors. The AHA has mentored career development awards for early career faculty that are something the NIH should have an equivalent kind of award for.

Make the minimum NIH effort for each grant 35% for single-PI grants and 25% for multi-PI grants (or something to decrease the number of grants that go to senior PI's). Increase the funding level of individual R01's some to make up for the lesser number of grants available to PI's.

Response 1512

Proven or promising external resources or approaches

No response

Perspectives on the postdoc roles and responsibilities

I initially saw the postdoc as an opportunity to learn new techniques and add tools to my repertoire. After 1 year in the position I now understand that it is simply indentured servitude for anyone with a Ph.D. and no real guidance as to how their skills are applicable in industry. As a postdoc I expected to have graduate students and undergraduates working under me so that I could take a more broad approach to my research. I thought that it would be good training to become a principle investigator. Instead, it feels like I am starting my graduate training all over again. I have no one working on any project remotely related to what I am doing in my present lab. I am required to work 7 days a week to maintain cell lines and experiments. I am required to build protocols from the ground up with little to no guidance (less than in my Ph.D.). There is no structure. The PI controls collaborations, funding, and my salary--due to the structure of T32 grants I am currently being paid less this year every paycheck than I was last year.

I am not trained to be a teacher. I am an expert in a specific field. I do not want to be used to teach or supplement the learning of students that are paying upwards of $70K in tuition annually without being compensated for my time--which takes away from the bottom line of NIH funding in the first place.

Fundamental issues and challenges

1) There is NO structure to a postdoc. PIs are allowed to simply use us as skilled graduate students. There is no direction in our contracts and there is no guarantee that we will be using our hard-acquired skills in our new lab--even if we are told this in interviews. We are told we are wanted for our expertise, but we are really just wanted for our fine-tuned hands.
2) Postdoc pay is NOT competitive. Institutions and PIs are left out to dry by the NIH because funding has no been increased for R01's--they are not on pace with inflation and industry has to charge more for consumables to sustain itself. Furthermore, as inflation has increased over the past 2-3 decades, postdoc salary has not kept pace.
3) To be a postdoc is to be a slave. As a first generation US-borne postdoc I feel as though I have been lied to. The postdoc salary is not enough to support someone that is vastly approaching middle-age. I am trapped because I have no "real" work experience and industry does not want someone who "has been in school too long."
4) To be an international-borne postdoc is to be a prisoner. My colleagues who are here on visas from other countries are not allowed to seek other employment without sponsorship. This means that losing their postdoc position--even if it is abusive--will cost them their legal status in the US. PIs threaten their status when they are dissatisfied with work products.
5) The career opportunities for academic postdocs are nil beyond becoming a professor, SRO, or non-tenure track employee at a university. It's simply a poor decision to make that is forced upon nearly every single graduating Ph.D. in the US. Our responsibilities are so broad and vague that industry cannot see our value.

Existing NIH policies, programs, or resources

1) Get rid of T32s and T90 grants. They need to be completely restructured. They are meant to train us to be successful, but the "training" we receive is bureaucratic rather than practical. I've personally sat through more "ethics trainings" because of bad actors that are currently funded by the NIH than I have sat through trainings that will support my development as a thinker and a technical expert. The funds should be used to teach us techniques and purchase supplies to support our own interests rather than simply take the cost burden of a student or postdoc off of an R01 or department account. There is zero benefit to me.
2) Restructure who gets grants. Overhead costs are ridiculous. The institution should support the PI and stand by their research. PIs should not be writing grants to pay themselves. Institutions should be the ones begging for money as they take >50% of the total cost to the NIH in overhead. Make institutions (not grants) pay postdocs as employees with hard-earned doctorates.
3) Perhaps create a sustainable staff-scientist role for people with PhDs.or without them that are capable of doing day-to-day lab tasks.we run the labs anyways.
4) Get rid of the idea of a "program." A Ph.D. should be awarded to someone that makes a SIGNIFICANT contribution to science. Not just anyone that completes a program. You need less Ph.D.s so you can pay us more.
5) Give us employee status.You need to stop giving universities free money. Undergraduates are not supporting their income.grants and tax-free endowments are. Postdocs and PIs are not paid by universities as much as universities are paid by our grants. Universities should be responsible for acquiring funding and then required to spend it on promising PIs and postdocs.

Proven or promising external resources or approaches

1) Grants that are awarded to low-income individuals during undergraduate education should be available to postdoctoral scholars. Our salaries are too low. Unless you have deep pockets, you will not be able to support a family or your spouse. This is a "rich-MANs" sport.
2) Trade schools are perfectly capable of teaching lab technicians how to do basic biochemistry, field data collection, and other repetitive (but incredibly important) tasks in research. There is NO reason that a lab should have to employ someone with a PhD. to do manual labor. We are trained to think.and we hardly get to because of the sheer amount of manual labor required of us.
3) Utilize industry services for repetitive tasks. A PhD. is meant to train us to work smarter, not harder physically. Industry exists to automate and reduce the costs of repetitive tasks. Grants do not currently allow for the purchase of equipment that industry produces to make these tasks more manageable.
4) Pay us more. If you want more US-borne postdocs staying in the US and becoming PIs you need to recognize that our dollars don't go as far here as they do in other countries. This is why international-borne postdocs are so common in academia. It's easy to get a visa, and they can send money home and are supplemented by their own government to survive in the US during a graduate or postdoc experience.
5) Look at industry. People are treated as people. HR actually represents all employees and serves as a liaison between employees and the company. While there are drawbacks.it actually protects both parties.

Response 1513

Perspectives on the postdoc roles and responsibilities

Very important phase of a scientist career, it helps you build confidence that you can successfully run and manage your own lab, helps scientists equip with latest technical skills.

Fundamental issues and challenges

Extremely low compensation (especially if you have to afford child care) and benefits, too long often close to 40 years, before one gets an academic position,

Existing NIH policies, programs, or resources

INCREASE POST DOC SALARY that means an increase in the amount of funding to the PIs as well. Offer more career grades like teaching specialists etc that will provide more alternate ways of career

Proven or promising external resources or approaches

No response

Response 1514

Perspectives on the postdoc roles and responsibilities

The postdoctoral position provides an opportunity for a recent graduate to spend a few more years figuring out what they want to do with their career. For many graduate students completing a dissertation does not necessarily mean they are ready to immediately jump into a faculty position. Some are, but other are not. Transitioning to a postdoc allows one to establish independence, or figure out that they do not like the stress of that independence, in which they may could choose to go into industry or work as a research scientist. The postdoc is also a time to learn new a new skillset, which could be related to benchwork, grant/research writing, or statistical analysis.

Fundamental issues and challenges

Because you are not an independent scientist yet, postdocs are wholly reliant upon the funding or data availability of their mentor to succeed. You can have a great idea for a project or 'next step' based upon your dissertation, but without start up funds you are often unable to pursue this idea, unless it just so happens that your new mentor is also interested in said project AND also has funds beyond just

supporting your salary (or you receive extramural support from a F31 or similar mechanism). The thing is, with how many people graduate with PhDs nowadays, the odds are that you won't find that match.

As a postdoc you are juggling so many different things from what your mentor expects of you, lingering PhD projects, and also trying to carve out time to make a future for yourself. The last part is probably the most important thing, but its often the one postdocs spend the least amount of time on because they are trying to just stay afloat.

Existing NIH policies, programs, or resources

First off, salary thresholds need to be updated more frequently. With how volatile the market has been with consumer costs, the salary thresholds should be updated on a semester (fall/spring) basis. Although updates would feasibly 'kick in' only when individuals are hired or renew their contract, having more frequent updates prevents the role from lagging behind cost of living. Furthermore, these salaries are often used as an excuse for faculty to pay their postdocs less than would be appropriate for a given location. For example, the first year minimum salary for a postdoc is going to go a lot farther in Texas than it is in California.

Secondly, one of the biggest struggles with postdocs is the move to a new location for that first postdoc. While faculty can often negotiate for a moving stipend, this is not at all a norm for postdocs. I can recall at least 4 different accounts (out of 6 cohort members) where we tried to ask for a moving stipend but were summarily denied. Having a funding source through NIH that could provide this assistance would be great, especially since new tax laws have restricted deductions for job-related moving to only those in the armed forces.

Finally, it would be awesome to see a funding opportunity for smaller scale projects that is not so labor intensive to apply for. I'm talking one year awards on the scale of $10-$20K that are not about providing salary support, but are just funds to support postdoc projects prior to a larger R21, R03, or R01 submission.

Proven or promising external resources or approaches

No response

Response 1515

Perspectives on the postdoc roles and responsibilities

The postdoc position should serve as a stepping stone to gain additional technical skills, develop independence as an investigator, and instill professional training in the individual.

Fundamental issues and challenges

Incredible financial burden, mental and emotional burnout, barriers or complete inability of healthy work-life balance and/or having a family, very little guidance or respect for career development beyond traditional academic paths

Existing NIH policies, programs, or resources

Payscales should frankly be doubled to accommodate the financial burden and expertise of postdoctoral scientists

Proven or promising external resources or approaches

Utilizing and encourages industry partnerships for training and overall greater crosstalk between academic training programs and industry

Response 1516

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

- Bad salary and underpaid (Why do a computational postdoc if you can make 100k more every single year as a computational biologist in industry? That is the difference between academic postdoc salary and my peer's full-time role salaries (75k as a postdoc vs 150-200k)!)
- Total uncertainty (Why do you think your good enough to get a PI position? There's no guarantees this postdoc works out the way that you want it to. If you get unlucky with your science—which, as science is hard, requires getting lucky!—then you won't get a PI position.)
- Work location in the present and future (Want to get a PI job? --> move to a select town/city with an elite research institution for your postdoc. Where do you want to live for your PI job (potentially the rest of your life)? If you're location restricted, e.g. due to family then you can only look at a couple institutions for PI jobs, and you hope that one happens to have a job opening and that you can get a job at one of them. An alternative? Work in industry—lots of companies in most cities/towns. Plus remote work is big, and you can work remotely from anywhere. Can you take an academic PI job and work remotely full time? Haven't heard of that yet, at least until you're senior w/ tenure.)

Existing NIH policies, programs, or resources

- Pay postdocs more. Narrow that gap w/ industry!
- Somehow enable postdoc-->PI prospects go up. e.g. K99s help awardees get PI jobs on the market, but the timeline isn't great. By the time I feel competitive for K99, I'm ready to move on (academic PI applications). why not a K99 straight out of PhD? have a set timeline for postdoc funding (e.g. 2-3 years) before it is expected that you have PI funding for 3 years. would be different than K99 and different than early independence. allows a postdoc to just pick up new skills rather than stress about getting papers before starting as a PI

Proven or promising external resources or approaches

No response

Response 1517

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

The issue is simple. Postdoc is very low pay compared to industry science jobs. Postdocs are seen as the pathway to become an assistant prof, but prof jobs are extremely limited and competitive, and often require the scientist to move across the country or further. These requirements are frustrating and a bit ridiculous for someone who has a PhD and spent their life committed to science. We just want to move forward science and feel valued with a good salary. But that is not an option unless you get a prof job.

Existing NIH policies, programs, or resources

The only solution is to make the position of research scientist more glorified. Introduce grants for research scientists to make six figures. Make research scientists feasible permanent positions at research universities. Allow research scientists to apply for R01s or similar NIH funding. This will also retain the most productive members of labs for longer. Otherwise, postdocs that don't get faculty positions will continue leaving for industry or other fields where they are actually valued with good salary an more reasonable work-life balance. Why wouldn't we? It's difficult being over 30, having worked weekends most of your adult life, and watching your peers in other fields easily make above six figures. Life as a postdoc has zero stability. We want to plant roots and start a family, but I might need to move to a different state soon? I have no idea where my life will lead next.

Proven or promising external resources or approaches

No response

Response 1518

Perspectives on the postdoc roles and responsibilities

I am currently at my second post-doc position, previously in New Jersey, now in [redacted for anonymity].

After 4 years in the previous lab I published (first author) very high-end papers, but I was made clear that there was no room to grow more in the same place.

In [redacted for anonymity] I see myself going on with the same determination but with no or very low perspective of being stabilized and become faculty.

I love the job that I do, but is not granting much no matter the impact factor.

Fundamental issues and challenges

Low salaries, insufficient for living with dignity in big metropolitan areas.

Sharing an apartment is no more an option, as I would like to create a family.but salary is barely enough to live as a graduate student.

Low professional ladder, with no pathway leading to stabilization, with implies no possibility to get even a mortgage.

Increasing requirement to publish at good levels, requiring a external network that often is unwilling to collaborate for data protection.

Literally NO BENEFITS.

Existing NIH policies, programs, or resources

Increase the number of fellowships and grants for young and growing Post-docs even if not faculty.

We are in a limbo, where we cannot apply for funds after 3/5 years after PhD, but to step forward we need to be faculty.

Portability of funds from an institution to another: funds should be more related to the investigator and not bound to the applying institution/lab/PI.

Proven or promising external resources or approaches

Talk about us.

We are NEVER called to express our direct voice.

Postdoc Associations are never ever heard at the table that matters, please invite them to share their requests during specific and dedicate meetings.

Response 1519

Perspectives on the postdoc roles and responsibilities

Postdoc position used to be an intermediate position before the tenure track positions, however due to the recent developments in the field of especially biology related sciences, a postdoc may reach up to over 5 years easily. This suggests that it should be acknowledge as a proper position with proper benefits. Postdocs are not able to even do any family plannings. They are taken advantage of and getting paid much lower than the other options (ie. industry, teaching etc).

Fundamental issues and challenges

Can you make any life plans if you have a contract of 1-2 years? You cannot even think of getting a bank loan because you are unsure of your future. How can one produce science with a pressure of financial limitations? Postdocs in academia are getting paid 1/2 or 1/3 of what they could easily get in industry. So far, we only continue because we are the older ages (over 30 years old generation). New generation is not as humble and resilient. The future of science in the US is at risk. Most of the science is done thanks to postdocs, and the least appreciated position is postdoc. Science and art goes where they are appreciated. All international people are flowing to the US because US used to be the place caring the scientists. Now, I am having difficulty to pay my rents with the salary I am receiving. I purchase the cheapest food. I have the most basic health plan. Why do I have to live in this situation? Even after postdoc, tenure track PI

position is so scarce. Why do I have to live in this stress? I will turn into early 40s when I have my tenure in the best case scenario. The amount of vacations I can have is 1-2 weeks at most which is to visit home country. I can very easily get triple amount of salary next month in industry right across the street. My very basic question is "Why do I have to live in this condition?" Answers is easy, I think it will be fixed, if not, thermodynamics will fix it, people will just leave academia and sciences, they will become engineers of biology at industry. It will affect the future of the country sadly. I hope you fix it before that.

Existing NIH policies, programs, or resources

Postdocs do not want more trainings. We have a PhD we can train ourselves if needed. We do not need fancy wordings and pizza parties. We need to be acknowledged properly and paid fairly. All our peers are getting the mortgage for their second houses. We cannot even afford a one bedroom apartments. Yes, American cities are great, American standards are great. Why do I care, I cannot even afford opera or a concert? Did you know I have to pick between either a dinner with friends or going to a movie, because I cannot afford both at the same month? Being pushed to make sacrifices each time in order to have even most basic pleasures of life is for sure what to improve first. Especially as international postdocs we are in a more difficult condition with 1-2 years contracts due to visa costs each time, to be have to go back to our home countries to get a visa each time.

You want suggestions, I give you the results:

Training ecosystem: Do nothing, give us travel budgets we can use, and we will train ourselves.

Academic research career pathways: No need for more talks or conferences on this, we see that our friends are working 3 times higher salaries, we already see the path, we see that our friends are offered a secured position in European institutes we already see the path. If you want postdocs to stay here 1—Give green card, 2—Increase the salaries twice for Boston region (and take into account geographical life-costs), 3—Make a Medicare type of social state approach for scientists ie. Scientist-care where our health insurances, retirement plans and children education plans are covered by the government

Science is not done under financial pressures, science is done with peace of mind and tranquility.

Proven or promising external resources or approaches

We are most of the time already over qualified for the jobs. Thank you but no need for more trainings. Give us the budget for traveling and open your infrastructure for postdocs for free and we are gonna come and get the trainings we need. This is already kind of happening via fellowships, grants from NIH. You can increase the acceptance rates and be more flexible for interdisciplinary trainings. This will be sufficient.

You really need to focus on how you are seeing postdocs. Even with all these questions you think that postdocs are machines to make better research for you. You think adding more trainings will make them happy and puffy. If you continue not acknowledging them, they are gonna move on to where they are acknowledge it is that easy.

Make a national postdoc ID card, use it as a starting point for postdoc benefits (ie. social, financial helps etc). Make it easier to stay on postdoc positions if researchers wanted to (ie. Staff scientist). It looks like postdoc is not an intermediate position anymore and it is actually a research position itself. Take all the postdocs that wants to work for NIH with stable job contracts as researchers. Then, they will at least feel like they always have an option in research and they will be more resilient towards difficulties that are going on today.

Response 1520

Perspectives on the postdoc roles and responsibilities

Postdocs contribute expert research skills to labs and push research projects forward. While the traditional views postdocs as being trainees in preparation for an academic faculty position, given the scarcity of faculty positions this model no longer applies in the vast majority. Instead postdocs should be considered expert staff for short term projects with a comparable salary.

Fundamental issues and challenges

Low salaries/stipends, lack of clear career prospects, poor work/life balance, toxic research environments. I will reiterate low salaries/stipends, as I think that this is the largest challenge in today's economy. Salaries across the research sector have not kept up with inflation and cost of living increases for decades

and the situation is now coming to a head with researchers at most career levels being unable to support themselves or their families. Low salaries for current postdocs is compounded by a landscape of low salary positions at the next career levels in academia, making the incentives to stay in academia for a career low to none.

Existing NIH policies, programs, or resources

NIH needs to revamp its grant structures to provide higher and protected salaries for postdocs and really any positions that are funded by soft money. Time and effort also needs to be put into the enforcing funding policies for academic institutions and ensuring that money is not being siphoned off for "fringe benefits" that may or may not actually being used to benefit the grantee(s). In my experience academic institutions take advantage of the grant system, taking large indirect costs, without clear support for the researchers that are bringing in the grants and suppressing researcher salaries to inflate institutional administration.

Proven or promising external resources or approaches

As the root of this problem is low government funding this issue is systemic across the country and there are not many functional models. A place to start looking may be at private research foundations that are less dependent on government grants for research funding.

Response 1521

Perspectives on the postdoc roles and responsibilities

My studies aim to convert non responders tumors into responders by combining basic tumor biology with preclinical knowledge and clinical needs.

It is very challenging and exciting work.

My ambitions are to acquire new advanced technology : imaging studies, therapeutic studies. and new research skills.

Fundamental issues and challenges

It seems to me be ok. I have no issues.

Existing NIH policies, programs, or resources

No idea

Proven or promising external resources or approaches

No idea

Response 1522

Perspectives on the postdoc roles and responsibilities

The role of an academic postdoc is to contribute to scientific advancement. Postdocs are typically referred to and treated as "trainees;" however, in my view and my experience as a postdoc they are typically independent scientists who are responsible for designing and driving projects, training and mentoring students, securing funding, and are integral to the day to day operations of the lab. While there is still training and learning going on by working under a supervisor, that is true of careers in all industries and postdocs are professionals who have advanced degrees and have worked in their field for typically at least close to a decade. I view being a postdoc as a job, one that is necessary to pay my bills and support my family as well as an opportunity to hopefully advance my career. Personally, I chose my postdoc in a lab that would allow me to improve my academic skillset but also in a location that would allow me to support my family and maintain a healthy work life balance. I think too much emphasis is placed on an unfair perception that postdocs need to sacrifice for the good of science to be successful and that we should be viewed as what we are, highly experienced professional scientists with the highest degrees in our fields.

Fundamental issues and challenges

I started graduate school immediately after graduating with my bachelor's degree and therefore entered my PhD and postdoc relatively young. When I first started my postdoc I was excited about making more

than the graduate student salary (especially since I stayed in a lower cost of living area); however, those feelings quickly changed when I realized how little it actually changed my ability to provide for my family and realize my personal goals. I have friends in many industries who all made more money straight out of college than I make as a postdoc now. Friends with no advanced degrees make 2x as much as I do with much more free time and better future career prospects. Every day I consider making a change to even a non-science job (despite loving my work) because I don't feel like I will be in a position to afford and realize my personal goals like having children or owning a home with the lost income potential from working as a postdoc. We work long hours, 7 days a week, doing the work that makes our labs run and get no respect to show for it. In my department we had to form a postdoc association to even get our pictures on our website, we don't get the same benefits as employees, and we are constantly forgotten about when it comes to department planning. We have the highest degrees in our field, with many of us having great training and publication records but are treated like entry level employees because we are "trainees." One look at jobs in any other industry for people at our level of success and training make it very obvious why there is a problem with recruitment and retention. Love of science doesn't overcome need to live.

Existing NIH policies, programs, or resources

Universities should not be allowed to hire postdocs on this "independent contractor" type basis where they are free to not give them employee benefits. It is ludicrous that postdocs can be in positions that don't give retirement benefits. This is especially bad for trainees like myself on T32 grants who get paid stipends that prevent pre-tax investing and also force us to pay taxes on health insurance subsidies.

Childcare is another huge issue for postdocs due to the typical age that they are started and even for grants that do give subsidies for childcare the amount offered is laughable.

Anything that can aid in the transition of postdocs to their future independent careers, especially when those programs decrease the time spent in a postdoc. It is taking longer to publish and even getting preliminary data for grants seems to take years in certain fields and putting restrictive time limits on grants and programs makes it difficult for early stage postdocs and makes you feel like you are always under pressure. Couple that with the limited number of academic positions available it creates an unnecessarily stressful time while you are trying to get useful data, learn about and apply for grants, and also potentially support and care for your family.

Proven or promising external resources or approaches

Look outside of science on how other industries treat people with lots of experience and advanced degrees. Why don't top engineering and tech companies have trouble with recruitment? If you want to improve recruitment, focus not on the science but on the people doing it. Better work will be done when the workers are less concerned about how they are going to be able to live. We want to attract the best people not the people who are willing to sacrifice the most, offering improved wages and benefits will not only increase the pool of applicants you have to choose from but will also make science more inclusive and prevent this career from becoming one that only the wealthy can afford.

Response 1523

Perspectives on the postdoc roles and responsibilities

In my opinion, the postdoctoral position is a stepping-stone experience from graduate student studies to a long-term professional career. It provides the necessary in-depth, focused training in ones particular field of interest. In some cases, the postdoc experience is an opportunity to learn new techniques, and/or expand their knowledge in a particular field with much success. They are also allowed to apply for internal/external funding opportunities to fund their research as well as engage in successful research dissemination. In other cases, postdocs are treated as glorified graduate students with minimal pay, and not given opportunity to apply for funding and limited opportunities for research dissemination. These experiences are dependent upon the principal investigator/primary research mentor and ultimately the institutional environment.

Fundamental issues and challenges

As a US citizen I have not had to worry about visa issues, but several of my colleagues who are postdoctoral trainees have had a challenging experience with visa issues. Most particularly their primary mentor will use the postdoc's visa (and renewal) as a threat to push their research (the PIs) forward,

keeping the postdoc from advancing in their own careers and training in order for the PI to meet critical career benchmarks or research deliverables.

Aside from the above issue, postdoctoral trainees are under considerable amount of pressure with long hours (50-70+ hrs/wk), minimal pay(!), lack of job security, medical/mental health benefits, family/childcare benefits, paid time off, combined with having to deal with microaggressions, discrimination, and bullying. These challenges contribute to the lack of recruitment, retention, and overall quality of life forcing postdoctoral trainees to seek other careers.

Existing NIH policies, programs, or resources

Accountability! The individuals (administration and PIs) responsible for training the postdoctoral trainees need to be held accountable for their actions against the inhumane ways they treat trainees and the only way to do this is to enact policies and programs reproving their actions. Mentor training should be REQUIRED for all PIs who are funded by federal government money (e.g., NIH/NSF/DoD grants). In addition, a funding scale should be implemented based on reports filed against the PI—for example, if a PI has multiple (verifiable) reports filed against them, then based on certain criteria, they will get less funding distributed than another PI who has an excellent record.

Postdocs should be able to voice their concerns without fear of retaliation from senior researchers. Currently, there is no mechanism in place where postdocs can file complaints or concerns and know that it will not be in vain, but rather that something will be done, whether it is a formal investigation or the postdoc has an opportunity to leave and receive training somewhere else without fear of risking their reputation or being black-balled.

Proven or promising external resources or approaches

No response

Response 1524

Perspectives on the postdoc roles and responsibilities

Postdoctoral training is an important period for researchers to transition into independent investigators.

Fundamental issues and challenges

Lack of an affordable living wage and benefits for academic postdocs. The current pay scale is so low that more researchers leave academic settings.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1525

Perspectives on the postdoc roles and responsibilities

It is a research scientist position that allows you some freedom to explore a research question that one is curious about. Based on my observations, you can be expected to work as a lab manager and a supervisor to graduate students, meanwhile, you are expected to read the literature, design experiments, collect and analyze data and create computational models that explain your data. In industrial postdoc positions, this seems to be more organized, where scientists only are responsible for tasks relevant to their core skill set.

Fundamental issues and challenges

Based on my observations, it looks like academic postdoctoral positions are expected to work in a job that would be divided into a team in an industry setting. The total compensation is way below compared to postdoctoral positions in the industry or around one-third of an entry-level scientist position. Additionally, the benefits the universities provide don’t match up to job market standards, such as a comprehensive healthcare plan with dental and vision insurance, family support such as adoption or surrogacy benefits, and childcare support, unlimited paid time-off, and flexible working arrangements. Anyone in my circle is

rigorously looking for research scientist positions outside of a university due to unsatisfied basic needs, and whoever lands a position immediately leaves their lab.

Existing NIH policies, programs, or resources

Allowing internationals to apply and compete for NIH fellowships may lead to retaining a fraction of them in academic research. To retain US citizens, debt cancellation and matching salary and benefits to industry settings can make it attractive to stay in academic organizations.

Proven or promising external resources or approaches

People don't want to live in poverty after years of training. Why would they make 50k with limited benefits, when they could make 150k with actual benefits doing the same research, but for a different organization? Match total compensation to industry pay scales, or there will be no one left in a university in 10 years.

Response 1526

Perspectives on the postdoc roles and responsibilities

Postdoctoral training gives a way to acquire further career goals in academy or industry.

Right now it is a sacrifice in personal and financial life to get a better position in future, to fulfill postdocs scientific interests.

Fundamental issues and challenges

PIs don't have any negative consequences for their postdocs career failures. Which leads to any kind of abuses.

Postdocs are completely dependent on their principal investigators (PI). This monopoly on postdoctoral trainee future leads to corruption:

Postdocs have to obey PIs for further career advancement—if not, then their chances to secure next position almost zero.

If PI don't have any incentive for postdocs development, postdocs are abused just as cheap labor force.

PI plays a great deal in postdocs career development—unlike industry, where market is less corrupt where people getting hired for their skills and not because of their PIs

Postdocs who decided to stay in academia having extremely high competition due to high number of postdocs and low number of advanced positions on the market.

Many academic positions have more than 2000 applicants per position.

Postdocs have only PIs as a role model for their development, which limits their view on their career paths.

Extremely high job insecurity for postdocs:

Feeling that we can be fired at any time, we have to please PIs to advance in our careers

Have to change their location on position change every time plus extremely high working hours leads to no personal life, postdocs are very poor choice as a life partners

Existing NIH policies, programs, or resources

First of all NIH policies, programs and resources should be known to postdocs.

Postdocs are working 12hrs a day and in many cases without weekends—they don't have time to read that is not related to their research.

Postdocs should have secured job position, if not then adequately compensated:

Salary in industry for the same position are 3x times higher and they have job contracts. Postdocs have low salary and no job security, plus extremely low chances to get higher positions in academia.

These programs should give a clear view on postdocs have a future career.

Proven or promising external resources or approaches

improving postdoctoral recruitment:

Postdocs should have a clear career paths. Right now they are hired and left abused.

Training:

- Training must be available for postdocs. Not is just working for their principal investigators, without actual training.

Working environment:

- Postdocs should have an option to have personal life. Like having partners, family, kids. Not possible right now—no time, have to move frequently, no money to buy a house or apartment (no money even to rent a studio and follow spending 50/30/20 rule).

Mentoring:

- No abuse should be tolerated. Now postdocs are just cheap labor force for their PIs. PIs don't have any negative consequences for their postdocs career failures.

Job Satisfaction:

- Postdocs should receive acknowledgements for their research, not just a name in the paper. Now this is abused by their PIs who claims all the research results exclusively to themselves.

Postdocs should have a light in the end of the tunnel, and this light should be for the postdocs as well, not only for their PIs.

Response 1527

Perspectives on the postdoc roles and responsibilities

In theory, a postdoc is a time to gain more training and learn how to manage a lab. In practice, this is not what I have always experienced. PIs often view postdocs as experienced labor (better than undergrad/grad student) they can get for cheap (not as expensive as career technician) and don't pay sufficient attention/prioritize the needs or goals of the postdoc. In general, I don't think postdocs should be in that position for the 5-10 that is about average in the US. I don't feel that there is much value added to my development as a scientist or as a group leader from my postdoc experience, except that the time is required for search committees to look favorably on my application to tenure-track positions and for me to accumulate more first author publications (again so the committees think I have "enough").

Fundamental issues and challenges

One issue I see with recruitment is the salary differential between academic/government postdoc positions versus going into industry immediately. Increasing the minimum salary for postdocs in academia/government would help, as well as allowing postdocs to be treated more like employees with benefits (saving for retirement, health insurance, child care, etc). Another big issue I have experienced, primarily related to quality of life, is the lack of training everyone receives in regard to mentoring. Bad mentors can completely ruin someone's postdoctoral experience, and I personally know a number of postdocs or former postdocs who have left academia or are considering leaving academia entirely because of this lack of mentoring. In a lot of ways, this mentoring issue is related to and compounded by the overall culture of science, encouraging overwork, being less than welcoming to women and/or minorities and/or people with disabilities, and negative competitiveness. Further, everyone is aware that there are many more grad students being produced than potential tenure-track positions available and many people are leaving postdocs early or not doing a postdoc at all because they are not interested in the highly competitive and unstable lifestyle of a tenure track PI.

Existing NIH policies, programs, or resources

I think PIs that are going to use postdocs in their R01 supported research should have to write career development plans for those trainees as part of the R01 application, like trainees have to do for F and K series fellowships. All non early stage investigators should also submit a letter from a former trainee talking about how good of a mentor the PI is. This would enable study sections/program officers to actually reward good mentoring as well as good science. There should also be more training available to

PIs and grad students/postdocs on how to mentor trainees and manage people. I also think that allowing postdocs or late stage grad students to practice the ins and outs of being a PI (grant and paper writing, mentoring, budgeting, organizing collaborations, managing people, etc) in "mini-PI" positions like the NIH Independent Research Scholars would be hugely beneficial to our training. I know many people who are very anxious about starting their own lab because there are so many different roles PIs need to take on that they have little to no experience in and allowing greater access to these kinds of positions would be extraordinarily helpful in preparing postdocs interested in academia/tenure-track positions for their future careers. I also think that acknowledging that there aren't enough tenure-track positions for all the grad students being produced and encouraging more career exploration early would help. Its possible that the grad student-postdoc-PI model is no longer viable and labs should move away from relying on postdocs to do the brunt of the science anymore.

Proven or promising external resources or approaches

No response

Response 1528

Perspectives on the postdoc roles and responsibilities

It is an opportunity to conduct independent research while benefiting from the mentorship of a senior scientist.

Fundamental issues and challenges

The NIH salary caps for postdoctoral positions are unfairly low compared to junior positions outside academia (or research institutes)! This is one of the biggest reasons for the migration of young scientists from academia to industry. A Ph.D. in a postdoc position earns less than a recent college graduate in the industry. Starting salary of a person with a PhD is around $72k—$100k, while a first-year postdoc earns less than ~50k.

Existing NIH policies, programs, or resources

Salary guidelines should be compatible with the degree and competency of the postdoctoral trainees. Match the salary to what is offered outside academia if we wish to keep young talented scientists in academia and research institutes.

Proven or promising external resources or approaches

No response

Response 1529

Perspectives on the postdoc roles and responsibilities

I view the postdoctoral position as the career scientist's analog to the medical doctor's residency. A step above prior training, more expectations and independence, and a deeper specialization with one's area. It's an opportunity to grow and be mentored in a new area.

Fundamental issues and challenges

Pay/salary is miserable. Postdocs in academia are pay well below contemporaries in other positions. Attracting and keeping postdocs is extremely difficult to do when industry offers, at a minimum, financial security. Recent cost of living increases make life as a postdoctoral scholar increasingly difficult. The feeling is postdocs are not meant to be retained. Our presence is temporary and our lives at our institutions are transient.

Additionally, postdocs are often ignored when it comes to institution-wide increases in pay, insurance, or other factors. We have very little protections when it comes to certain matters and are often forgot about or are unable to be properly categorized when it comes to university services or policies. Are we students? Are we staff? The distinction is rarely clear.

Existing NIH policies, programs, or resources

Guidelines for pay should be frequently updated to make postdoc positions more desirable and competitive. They don't need to match the extreme payrates of, say, silicon valley technology corporations but the current policies on pay level are unbelievably outdated and only get worse with each passing day.

Proven or promising external resources or approaches

Seriously, just pay us more and encourage institutions to treat us with the respect we deserve.

Response 1530

Perspectives on the postdoc roles and responsibilities

When I was applying for my postdoc I viewed it as an opportunity to gain advanced training in my specialty area, some experience in other areas that closely aligned with my ultimate career goals, and hone any skills that needed further development, with the ultimate goal of launching as an independent scientist. I thought this would be a great opportunity to publish a significant amount of papers, engage in professional development opportunities and networking, and write my training grant to help secure funding to get to the next step in my career. When I was accepting my postdoc position (which is funded by an NIH R01 at the top university in the US), I was told I would get all of those things and more. Now, I see my postdoc as a glorified research assistant position. Instead of getting the experiences I wanted (and that were sold to me during the interview) I am responsible for things that typically an undergraduate or post-bac RA would help with, collecting data, analyzing data, managing databases. The only experience I am getting that I wanted was publishing. However, I am treated essentially as a publication factory on top of the RA responsibilities that I manage. So this leaves me no time to further my career, develop any training grant ideas (or write a training grant), or engage in any independent research of my own. All of my time is dedicated to the research activities of the lab, and there are no research supports (research assistants, volunteer undergrads, etc.) in place to even help with these duties. Yet, my PI and the Co-PIs on this grant receive .25 FTE and only show up to a 30 minute weekly meeting maybe? If I had to sum up my experience I would say, exploitative.

Fundamental issues and challenges

First, the pay structure for postdocs is insulting. Yes, postdocs are technically "trainees" but we hold advanced degrees and have years of technical training. (Also, the argument could be made that the vast majority of us aren't actually receiving training.) In many cases, RAs who hold a bachelors degree and have far less research training are receiving the same (or sometimes more) salary than the postdocs in the lab because of the NIH postdoc salary structure. In fact, my PI has stated that because of the NIH salary structure and the benefits packages it is actually "cheaper to hire a postdoc than a research assistant and you're getting someone with more specialized training." So the PIs KNOW that they are exploiting postdocs for cheap labor. And the fact that postdoc salaries aren't at least adjusted by location is even more insulting. I work 70 hours a week for $3500 a month after taxes in Boston. How am I expected to save for my future at all, pay basic living expenses? How do postdocs with families support themselves? Second, the current structure in place for postdocs makes it beneficial to the PIs to keep us as long as possible. If postdoc positions actually did what they were supposed to do, and launched you into the next stage of your career, then the financial sacrifice for a couple of years might be doable (not fair or ethical, but doable). However, because the PIs know that it's to their benefit to have postdocs instead of RAs, they don't put any time into training us or helping us to launch. Instead, they bring us on as essentially RAs to run their studies and crank out publications, leaving us no time to develop our own careers, and don't assist us along the way at all.

Existing NIH policies, programs, or resources

The salary structure for postdocs needs a major overhaul. If you're going to provide the same salary based on years of experience, then it at needs to be at least adjusted by location so people in Boston/NYC/large metropolitan cities are able to actually live on their wages after they worked for 5+ years to get a doctorate. On USAjobs, positions that require a doctorate are paid at GS11, which has a starting salary in the $77k range, which is far above the starting ~55K that a postdoc makes. We also need more accountability for PIs who bring on postdocs. I was never given a formal IDP. My contract was renewed without consulting me and without any formal performance review. There need to be strict systems in place that show the PI has the time to contribute to training postdocs when they apply for NIH

funding that has effort written in for a postdoc. If a PI has multiple R01s (like mine), plus additional foundation grants and teaching, where will they have time to train the four postdocs? The answer is that they don't. So there needs to be a system in place when researchers apply for NIH funding and include postdocs in their budgets where they describe how MUCH time they will dedicate to training a postdoc, and what activities a postdoc will assist with, and what activities a research assistant will assist with. Then, there needs to be some oversight to ensure that the plan is being enacted. For example, perhaps a PI needs their trainees to submit a report of their activities and the training they've received as part of their RPPR? Anything to protect the postdocs and make sure they aren't being exploited.

Proven or promising external resources or approaches

I think this survey is an important first step. And I would love to see a qualitative analysis of the findings of this survey. I have no additional approaches to offer.

Response 1531

Perspectives on the postdoc roles and responsibilities

It is a transitioning position for high qualified intellectual workers.

But I don't really think we need a transition and postdoc is not the place to learn how to do research, because this is what PhD means. Postdoc is as is time to apply and improve our skills, because learning never ends. Everybody is constantly learning.

So, sometimes I see myself as a postdoc like "I don't know what to do next, so I'll take this position to have time to figure it out", but sometimes it really feels like "it is hard to find a job with my qualifications, let's take this position until I find a good one, unemployment is not an option".

As a Brazilian, I never thought that I needed a postdoc to be a faculty, because theoretically we don't need it. However, the competetion is increasing quickly, not only because maybe we have more postdocs but because we have less postitions? In summary, I think that the reason why PhDs need a postdoc now is because when there is a faculty position opened, PhDs will complete with postdocs that will have more experience and accomplishments. It is more likely that a postdoc will get academic positions. So, I need a postdoc to be better prepared, and a competitive candidate for a faculty position.

When I started my postdoc being hired after an open position, I felt like I was being a research assistance without a real research project, but collecting data. The situation changed when a project came out and I worte my first fellowship project, althoug I haven't received a fellowhsip yet. I think some principal investigators can treat their postdocs like data generators rather than investigators that have hypotheses and questions of their interests to ask and test.

Fundamental issues and challenges

Salary level: the income is low when compared to industry jobs with same qualifications. Salaries of biomedical postdocs are very low compared to salaries of postdocs in engineering, technology and computational fields of research.

Lack of training and mentorship for postdocs who pursue a career in academia. Training should be as important as research and lab work per se, and mentorship should be taken seriously.

Existing NIH policies, programs, or resources

Many grants and programs are only for US citzens and as being a foreigner I can't apply for most of them.

Proven or promising external resources or approaches

Education is crucial. I benefited substantially from a workshop offered by NIH on grant-writting. I think that initiative should be part of NIH efforts in a regular basis. I guess we also need mentors that care about training their postdocs, therefore, NIH needs to motivated them. Awards for faculty mentors is a good way to increase awareness of this important issue.

Response 1532

Perspectives on the postdoc roles and responsibilities

As someone who did a postdoc for 1.5 years before transitioning into a state government job, here are my perspectives. The "goal" of a postdoc is to allow someone with a fresh PhD independently perform research under the guidance of a seasoned mentor. This can be useful in several cases, such as switching fields and needing more training in a specific area, gaining experience at a different institution with potentially different resources, or experiencing a different style of mentorship. The ideal timeframe is probably 2 years, at which point the postdoc is ready to enter the academic workforce. The mentor should be helping the postdoc find job opportunities, establish a research and teaching plan, statements, etc, and utilize their connections and experience to help the postdoc move on to their next position. Since papers are the currency of academia, publishing should be a priority as well. The postdoc should be given the same amount of resources as a new PI would, as ostensibly they are training to be a PI.

The benefits of the postdoc position only apply if someone is financially supported in other ways (family, spouse, etc) AND is looking to become a professor. Otherwise, directly entering the workforce into industry or government is financially a much better decision.

Fundamental issues and challenges

The main issue with the postdoc position is the low pay. If someone is not looking to be a professor, a postdoc is generally not useful and is financially a very poor decision.

Retention should not be an issue for postdocs, as the goal is not to keep them for a long time—the position is specifically a transition and should not last more than 2-3 years. Postdocs should not be staying in one lab for 10 years.

Quality of life for postdocs is poor for several reasons: low pay, lack of support and comradeship, lack of job security, and more often than not, overwork. Postdoctoral pay is not to scale with the economy and is definitely not competitive with industry or even government positions. The lack of cost of living adjustments for expensive cities is even more damaging and creates situations in which some people may not be able to afford to do a postdoc at elite institutions in expensive cities such as Boston, New York, and San Francisco.

As a grad student, you have other grad students in a cohort to develop comradery with. Postdoc'ing is an incredibly isolating time, as you are not involved with the grad students or the faculty and are often not considered a full employee of the university and therefore cannot receive benefits such as retirement. Often the position is unstable and dependent on funding, adding stress. Additionally, as a postdoc often you are expected to perform an experiment beginning-to-end without any additional help, and therefore end up working greatly more than 40 hour weeks. Particularly toxic PIs may try to keep postdocs in their lab for longer to exploit their work.

Existing NIH policies, programs, or resources

The salary level for postdocs that is set by the NIH should be increased significantly to be competitive with industry/government and should account for cost-of-living adjustments in expensive locations.

Proven or promising external resources or approaches

A substantial increase in base salary

Perhaps a system of "rating" the conditions in a lab as a postdoc, or an effective system to report abuses by PIs (and consequences for those reported).

An overtime pay system

Training guidelines for PIs—i.e. what the postdoc should be able to do upon leaving the lab (e.g. finding an academic position, publishing papers)

Guaranteed retirement benefits

A postdoctoral association, union, etc for comradery between postdocs.

Response 1533

Perspectives on the postdoc roles and responsibilities

A post-doctoral fellow is a training position that prepares an individual for their role as an independent investigator after completion of their doctoral degree. It is an opportunity to go into a new area of research or system and to master new approaches that will be critical for transitioning into a faculty position.

Fundamental issues and challenges

The lack of funding for research and the limited number of faculty positions is resulting in fewer PhD students wanting to pursue post-doctoral studies. Industry is now hiring PhDs directly from their graduate programs and so there is less of a need to pursue post-doctoral studies. Writing grants and low pay are the top reasons why individuals tell me that they do not want to pursue a career in academic medicine.

Unfortunately, our PhD students and post-doctoral students see how hard it is to get funded for our research and this is discouraging for them. When I was a PhD student, during Clinton, it was much easier to obtain external funding and this never factored into my career choices. The lack of funding for our research is draining our scientific talent from our institutions and preventing scientific advancements. In addition, the emphasis on "translation", and not basic science, is a missed opportunity for important fundamental discoveries to be made.

Existing NIH policies, programs, or resources

Being a post-doc correlates with when individuals would want to start a family and sometimes money is a primary concern. In terms of graduate education, more of our students have masters degrees or take a few years off to work as a technician before starting graduate school. This means that individuals are older when they finish their PhD and may be starting families or have student loans to pay back. One idea is to help to offset childcare costs for post-doctoral fellows and for graduate students as well. When I was a post-doctoral fellow at [redacted for anonymity], my salary was less than my children's subsidized university childcare and so I was actually negative salary without paying for rent or food. This is a major issue for women in science.

The other issue that I faced as a post-doctoral fellow was that the cost of living in [redacted for anonymity] was a lot higher than other parts of the country and yet the post-doc salary was the same regardless of where you lived. That meant that I had less disposable income to pay for basic necessities. This is something that could also be easily fixed.

Lastly, more programs, like the K99/R00 (in which I was a recipient in its early days), is critical for the transition to an independent faculty position.

Proven or promising external resources or approaches

Unfortunately I have no good models to suggest.

Response 1534

Perspectives on the postdoc roles and responsibilities

The postdoctoral position is a training position that diverges from being a Ph.D. candidate in that the responsibilities and individuality expected are at a higher level. Postdocs are asked to completely drive projects forward and often mentor graduate students or research associates in the lab. In this way, they (in theory) are afforded the opportunity and training for establishing themselves as an expert in a field and ready for the next step. However, in reality postdocs are often exploited and underappreciated by their PIs.

Fundamental issues and challenges

The #1 fundamental issue inhibiting recruitment and retention is in pay. Postdoc salary range of $55k is nowhere even close to the entry-level industry scientist pay of $110-120k. As such, how can postdocs justify spending time in those positions, especially in very high cost of living situations or in the event they have to care for a family member? Moreover, coupling the low pay with the often abusive nature of PIs with postdocs, it makes the job just not worth it. Even further is that every postdoc knows that there are an extremely finite number of faculty positions available and very low odds of obtaining such a position.

Given that, there doesn't seem to be a reason to stay as a postdoc for a very long time at all when industry scientists make double the money with no requirement for postdoctoral training. For many scientists, even doing the postdoc in industry is preferred given that it gets their feet in the door of an industry job while still earning more income than a standard university can provide.

Existing NIH policies, programs, or resources

Both the publishing and grant systems need to be overhauled, given the emphasis placed on both at such an early stage in the career. For instance, the K99 is often thought to be a critical grant to proving the ability to obtain independent funding, however if there were other mechanisms to obtain bridge funding between postdoc and PI then that would allow for less straight-line postdoc-to-PI transitions. Furthermore, there is a stigma surrounding publications as the 'currency' of academia yet I wholeheartedly disagree that publications are indicative of someone's ability to do work. For many PIs, publications are often given as incentives/promises to join a lab, adding someone as an author with very little work done to earn this authorship.

Proven or promising external resources or approaches

Too little accountability is held for abusive PIs in that Universities are actively encouraged to cover up any deficiencies because it directly affects their bottom line. A PI can often abuse multiple generations of graduate students and postdocs while suffering no repercussions from either the NIH or the University. The power imbalance between PI and postdoc/graduate student often sacrifices the humanity for the research. A stronger accountability system tied directly to funding would keep both Universities and PIs honest about the way they conduct research.

Response 1535

Perspectives on the postdoc roles and responsibilities

I see my postdoc position as a temporary one. It's not something I can afford to be in for very long (financially and in my career), and I view it as a stepping stone to a more permanent career path in industry science.

Fundamental issues and challenges

Overwork, underpay, and very little chance of advancement in the academic science career path.

Existing NIH policies, programs, or resources

NIH funding to individual postdoc fellowships and grants should be increased.

Proven or promising external resources or approaches

No response

Response 1536

Perspectives on the postdoc roles and responsibilities

I view a postdoc as a stepping stone from PhD to faculty appointment. It is a great training stage to learn new techniques and/or apply them to a new field, and to develop more management skills prior to establishing a lab. I feel that this stage has really allowed me to develop my own independent research ideas and to learn which areas I really want to pursue in my future research program. However, I think this experience is highly dependent on the lab environment and the support of the PI.

Fundamental issues and challenges

Postdoc pay is far too low. I am at a crucial point in my career and comparing academic jobs with those in industry. Starting salaries in biotech (even without PhD) are far higher than postdoc salaries. This perpetuates exclusion in academia as only people who can afford to take the financial hit whilst in this phase can follow this path. In particular, this is unsustainable for people with dependents and for international postdocs.

I have also been disheartened by the lack of funding opportunities available for international postdocs here—I have often been sent information about schemes only to scroll to eligibility and find that I must be

a citizen or permanent resident to apply. There is no good reason for this. I pay taxes and would love to stay in the USA to establish my lab, so why can I not participate in schemes like the T or F grants? This also creates a more hostile environment for international postdocs and disadvantages us in terms of career development. To my knowledge, only the K99 is available and I had already aged out of that by taking a postdoc in Europe prior to moving to the USA.

Existing NIH policies, programs, or resources

Expand grant schemes to fund international scholars.

Increase postdoc pay scales.

Increase the funding awarded to R01s (especially modular budgets) to allow for increased postdoc (and PhD!) salary.

Guidance on visa options for postdocs—some universities are better than others, so a centralized information point would be great.

Proven or promising external resources or approaches

Additional training opportunities in project management, negotiation skills, strategies for successful collaborations, mentorship etc. This could form part of a broader NIH "Future Leaders" type scheme that provides career development support for postdocs who want to stay in academia and, in doing so, simultaneously improve mentorship for the next generation of PhDs and postdocs.

Response 1537

Perspectives on the postdoc roles and responsibilities

Training program that is designed to provide research scientists with more experience in independent roles. Mentoring aspects simulate the advisor-advisee interactions they would have during a PI position. It is a position of increased work and responsibility, but also allows the freedom (possibility) for making mistakes in a controlled environment, allowing for increased learning opportunities. The postdoc has an opportunity to investigate avenues or research to truly understand what type of career they want (i.e., is academia the right choice for them).

Fundamental issues and challenges

Hours: This is a position that requires many hours of work, typically well outside the 40-hr work week.

Salary: There is a national standard that is equal regardless of location. Postdocs in Los Angeles get paid roughly the same as those in Kansas. The former has a much higher cost of living, either prompting living in unsafe environments and/or living with other individuals. Either situation can prove mentally and physically challenging.

Authorship: As a recent graduate, postdocs will be "fighting" for first-author positions to help launch their career. In the same breath, graduate students are doing the same to help launch their career and/or secure a postdoc position. Regardless, there are typically not enough projects within labs for both groups to secure first-author positions, often leading to conflicts and eventually lack of enthusiasm for higher academic positions.

Existing NIH policies, programs, or resources

Speaking on previous comments, if existing programs are not implemented nation-wide, but region specific and tailored to those areas (e.g., Los Angeles vs Kansas). Additionally, each of those communities have unique extracurricular interests that help shape the community and research activities of those academic institutions. For example, underserved communities is a bigger concern in downtown Los Angeles and in Manhattan than it is in upstate New York or even Hawaii.

Proven or promising external resources or approaches

I feel most of the concerns that I hear from postdocs in a larger city are centered around pay. Most are content/complacent with the long hours, but not being able to enjoy life outside of these hours is hindered by costs of living. The research interests of the postdoc will guide them to certain labs, but they are most often deterred by cost of living in big cities. I, personally, have had individuals decline for these reasons. There may be resources out there that address this, but making them more apparent might be beneficial.

Response 1538

Perspectives on the postdoc roles and responsibilities

I view the responsibilities of a post doc position as: conduct experiments under the grant of a PI, train and mentor graduate students, write their own grants as well as edit grants with a PI, managing and balancing multiple projects for multiple members of a lab

Fundamental issues and challenges

No work/life balance (i.e. hours and work load is often the same if not more than that of a PhD, leading to burnout and loss of passion for the sciences/field that I was initially interested in). BIGGEST factor in my opinion is money/pay: Postdocs are overworked and underpaid, whereas more lucrative (often 3-5x the salary of a post-doc) and less demanding industry positions are more favorable to those exact points. Traditionally, postdocs were 2-3 years and then the individual moves up to a faculty position. Now, it's more common for post docs to complete 2 or even 3 post docs before moving up to a faculty position, which is more time being financially deprived and overworked than before.

Existing NIH policies, programs, or resources

More grants that can financially support a family as they enter and transition up the academic chain (i.e. child care grants, help with home buying/home owning near the institution grants, etc.). It is often financially impossible, especially in this economic climate, for an individual to start or even grow their family on a post doctoral salary unless their partner is also a working parent and is a very lucrative job position.

Proven or promising external resources or approaches

More mentor/mentee feedback, job satisfaction, transparency during recruitment of what the post-doc journey would look like (i.e. hours, pay, expectations), and outreach to senior graduate students to ask where do they lean (academia/industry) and why—this specifically would help to prevent a post doc shortage instead of reaching the pool of PhDs that are in industry to go back to academia.

Response 1539

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

Salary and benefits seem like the biggest ones. At least half of the people I know who didn't do a postdoc after graduate school chose industry instead solely due to higher pay, retirement benefits, and less demanding hours. They likely would have preferred a postdoc if these things were more comparable between academia and industry.

The remaining people who didn't do a postdoc were a mixed bag, but generally this was due to things like a perceived inability to become a PI down the road or worries about postdocs being similar to graduate school but with more expectations/stress, which in combination with lower pay/benefits than alternatives, made other options much more attractive. Paths within science that don't end in a PI position would help, though this issue would also be substantially mitigated with better pay and proper benefits.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1540

Perspectives on the postdoc roles and responsibilities

The draw for me to become a postdoc is because I really want to be an academic PI. I love mentoring students, I love grant writing, and I love looking at samples on the microscope even at late hours of the

night. So I was going to do a postdoc no matter the cost because it is what one must do to get to that dream job I want and think I will be really good at. The pros and cons of staying in academia versus going to an industry job have been weighed, and my choice has been made, a choice I would make again. Postdocs are, in my experience, the true pioneers of new and creative ideas in scientific research. As a postdoc, I bring new directions and avenues of interest to my PI's lab. My faculty advisor then advises me on how to present these questions as interesting topics in grants, at conferences, and in papers. However, I see the postdoc as the expert on the topic being researched—the most fluent in the literature, knows the details of all the experiments, and has thought about where the project should go. I think postdocs need training in how to pitch their ideas and might join a lab to acquire new technical skills, but they know how to ask good questions and how to design good experiments. Postdocs are also extremely productive scientists because they are driven to succeed in the limited job market, feel very passionately about their chosen area of research, and have extensive technical/skills training in the PhD. Therefore, they are valuable employees in the lab, training graduate and undergraduate students, advising the PI on their grants, and leading a new avenue of research in the lab.

Fundamental issues and challenges

The main issue with recruiting and retaining postdoctoral trainees is the lack of competitive salaries and benefits in academic research. During my PhD, colleagues were graduating, taking industry jobs, and making at least twice as much as postdocs in the same geographic region. This isn't just something that "feels bad." This severely limits the ability to plan for the future regarding retirement and family planning. Furthermore, the lack of guaranteed academic faculty positions after a 5-6 year postdoc means you could just be putting yourself years backward in retirement savings without clear job advancement prospects. The financial stability risk is really high and is worth giving up the "dream job" of being an academic research scientist in a lot of cases. This is compounded by the fact that retirement planning is complicated even if you can save money in your postdoc because of the structure of F32 funding from the NIH. As an NIH fellow, I am no longer an employee at my institution, so I cannot take out pre-tax retirement savings despite having the financial ability to save some money each month. Some postdocs also suffer tax burdens because they must pay taxes on income used for health insurance benefits. Lastly, the explosion of biotech companies doing exciting scientific research makes moving to industry a much more enticing prospect for PhDs with interesting scientific questions. A decade ago when I started on this career path, I thought that the only industry job I could do was drug development, which I wasn't interested in. I have learned this is not the case, and there are a lot of really creative and interesting topics of research in the biotech industry such that leaving academia doesn't mean you have to give up as much creative license and passion.

Existing NIH policies, programs, or resources

First and foremost, postdocs should always be considered employees, either of their institution or of the federal government. I think the NIH could give all F32 and K99 recipients employee status, with health insurance and retirement matching. This standard would encourage universities to do the same for postdocs not on NIH fellowships. While this would be the ideal fix, one small change to an existing policy that would be helpful would be to change how health insurance payments are made to fellows. The NIH should set aside a budget of up to $15,000 solely for health insurance for F32 recipients that is separate from an expense budget of say $5000 for research purposes. Currently, if your child or spouse is on your health insurance it eats up all of your F32 supplementary funds. It's not fair that I have more money to spend on a conference and a computer, just because I have no dependents. Second, if the postdoc salary isn't going to increase, the NIH should at least allow PIs to budget some of their R01 money to top up postdoc pay if they want to, as this is currently not allowed.

Second, the minimum postdoc salary should be increased to better compete with industry positions and recognize the expertise and leadership that postdocs bring to their fields of research. I would recommend starting at $70,000 (the low end for entry-level Scientist I positions in biotech). This might mean fewer postdocs, which I think is ok. If postdoc positions are more competitive, the best candidates will occupy them. If those top candidates are stable and happy they will be the most productive. There are not enough academic faculty jobs for all the postdocs we have currently, so having fewer postdocs would make the long-term job prospects of each individual better.

Proven or promising external resources or approaches

Unfortunately, I don't know of any "proven" programs that help postdoctoral training. Perhaps a grant system to design and report on new postdoc training ideas would be beneficial. Departments could apply

for training grants that fund postdoc training programs and provide professional development skills for participants. This could also be a way for departments to adapt to higher salaries for postdocs. If a department wants to raise postdoc salaries they could write grants for NIH funding that would supplement those salaries outside of PI grants. They would need to provide a plan for how they will enrich the training experience of participants and use funds from the grant to both top up postdoc salaries and pay for professional development programming.

Response 1541

Perspectives on the postdoc roles and responsibilities

The academic postdoctoral role is predominantly focused on designing, conducting, and interpreting experiments in an effort to produce substantive material for conference presentation and peer-reviewed publication. Additionally, ambitious postdoctoral researchers seeking independence are often required to identify and obtain sources of funding in the form of grants, fellowships, or partnerships beyond what is offered by their PI. Experimental research productivity in the form of publications and grants are facilitated by developing a strong presence within a particular field of interest which implicitly requires the additional responsibility of networking in order to gain better understanding of the working relationships within a given scientific research field. An additional role is mentorship training/education of undergraduate and graduate researchers, particularly if career goals emphasize education and/or teaching, or if the lab PI is unable/unwilling to accommodate all trainees. In other cases, postdocs may advise or conduct experiments if their lab partners with private sector research groups or companies for a common goal. Ultimately, many of these responsibilities are not rigidly defined for each postdoc in terms of a checklist or deadlines and prioritization is incumbent upon the postdoctoral mentee as well as the postdoctoral mentor.

Fundamental issues and challenges

Income disparity compared to private sector employment alternatives inhibits postdoc retention and recruitment. Many pioneering research labs are localized in large coastal cities with high costs of living. Cost increases are often 2-3 times higher compared to other parts of the country, and postdoctoral salaries are rarely scale to match these costs. The cost of working in cutting edge academic research is significant, particularly for postdocs starting families. Established businesses and startup companies alike are offer a pay for PhDs which is often 2X higher than a starting postdoc salary. Importantly, these include potential for promotion/growth, whereas the postdoctoral income climbs at fixed increments regardless of performance. In some ways, this de-incentivizes quality output. If there is no financial reward for working harder, then working the least amount possible maximizes the earning per hour.

In contrast, many immigrants working in the US work very hard to stay in good standing within US academic institutions due to the threat of losing temporary protected status. This is particularly salient for postdocs from countries with economic/military conflict where motivation is strengthened due to the looming threat of deportation. For PIs, this provides an opportunity for fear as a motivating factor to keep foreign postdocs working too hard. This same fear of deportation contributes to preventing discussion of PI abuse (verbal, sexual, labor, or otherwise). American postdocs in these labs unwilling to meet the same standard of work often leave for industry jobs with a more realistic work/life balance without fear of deportation.

Another issue limiting retention of postdocs which also affects quality of life is the emphasis on specific non-transferable skills during training. These limit lateral mobility for jobs within academia and beyond. Many postdocs leave for fear that they will become unemployable due to the narrow focus of training and experience.

Existing NIH policies, programs, or resources

It is good that there are awards in place for postdocs to fund additional training (T32, F32), particularly in institutions with less funding where this can financially support incoming postdocs. Expansion of the number of these awards and financial scope of these awards (i.e. the alottment for salary) would greatly increase their utility. For universities and hospitals, employee benefits like health insurance are dependent upon institutional employment in terms of monetary compensation. Thus, for many postdocs getting a training grant or fellowship means losing the eligibility for benefits. Thus, recipients of an award often find that their salary actually reduces because they now have to purchase things like insurance at cost.

Ultimately, these awards would benefit from being able to increase postdoc salary beyond the amount allotted for research.

K22/K99 awards are good in principle because they provide a public stamp of approval for independent investigator status on the path to becoming an academic PI. However, can also be at odds with the postdoctoral/PI relationship because the time spent writing/planning and applying for the grant ultimately takes away time the postdoc has for their primary appointment. Ultimately, the reward will also involve removing key resources (i.e. the postdoc and their research project) from the greater lab environment. From the PI perspective, it would ultimately be cheaper and more productive to have a postdoc finish their training without wasting time on outside projects and grants, and would not generate future competition for scarce resources. Instead, a PI can get full-value from a postdoc for 4yrs without distractions. One improvement for the postdoctoral training ecosystem would be to de-couple these awards from the existing institution and PI, or to add additional awards for independence which can be applied for during the final years of PhD or first year of postdoc training.

Proven or promising external resources or approaches

Hybrid postdoctoral programs at established companies like Genentech, Amgen, or Roche provide good models for effective postdoctoral training because they provide five key elements which improve the training ecosystem.

1. The pay is more fair than an academic postdoc
2. the skills learned/employed are highly transferable beyond the specific research question at hand and
3. the training occurs under an experienced investigator and involve peer-reviewed publications in the field of interest and
4. subsequent postdoctoral training culminates with possibility of long-term or permanent employment opportunities
5. hard work has potential to be rewarded with additional personal growth or pay increases. Obviously, these private companies are distinct from many academic institutions. Nonetheless, providing these five elements would improve the postdoctoral training ecosystem.

In terms of improving postdoctoral recruitment and training, there need to be concrete steps taken to clearly distinguish the difference between graduate training and postdoctoral training which at this point are not very distinct. Pay is comparable, lab responsibilities are comparable, the working environment is identical, mentoring received is comparable, and ultimately both a PhD and postdoc tend to have very low job satisfaction. Clear ways to delineate these for postdocs are: increase salary, increase scientific independence, increase performance based rewards, and provide stable employment options for after the postdoc is over. These would likely improve the environment for PhD students and research assistants as well by providing a "light at the end of the tunnel". As it stands, the job itself requires a great deal of monetary risk, job insecurity, and stress which contribute to poor recruitment, retention, and quality of life for post docs. Creating new career incentives in the form of a higher salary, additional potential permanent research positions, or adding merit based achievements based on performance are steps in the right direction.

Response 1542

Perspectives on the postdoc roles and responsibilities

How I view a postdoc:

- Additional training meant to teach the individual to become a more independent scientist
- Opportunity to expand your knowledge (i.e. new techniques, new field)
- Crucial if you choose to stay in academic science, but not of value for pursuing other non-academic careers

Roles/responsibilities of a postdoc:

- One of the main scientific drivers of projects and the lab
- Mentor position within the lab, where you prior experience is used to help guide other people's experiments and projects
- Expected to bring in your own funding

Fundamental issues and challenges

This is a multi-variable problem that begins at the graduate school level. Getting into a competitive PhD program these days requires at least a few years of prior research experience, if not several co-authored papers. Fundamentally, this means potential PhD students are taking gap years after their bachelors degree in order to be competitive for graduate school, resulting in students who are on the older side when entering graduate school. By the time students graduate they are older, possibly married, or possibly parents. The value of a postdoc at this point is decreased, as alternative academic careers find high value in PhD's who also had prior experience even before entering graduate school.

This brings me to my next point which is postdoc wages are not competitive with up-and-coming non-academic positions (such as in industry). Starting salaries in other fields such as consulting can be $115k, and industry postdoc positions can even be in the $80-90k range during your first year. For students, who are looking for job security and wages to support things such as buying a home, a car, or children, a postdoc salary is not providing enough security for these other important life events.

Finally, postdocs seem to be of high value if pursuing a career as a PI. Given the constantly shrinking job market for PIs, and the constant uphill battle to be in the top 1% of scientists who can make it to this step, the need to do a postdoc seems like more effort than its worth (again given that other alt-academic careers value scientists who didn't do a postdoc).

Existing NIH policies, programs, or resources

Excluding international students/postdocs/scientists from many grants perpetuates is inequitable. Additionally, leaving the green card status of international trainees in the hands of PIs can lead to abuse of power of the PI. Several colleagues of mine are forced to work holidays and weekends because they are afraid of the green card status.

Proven or promising external resources or approaches

Yale's YSM Fellows program seems like a good start to addressing some of the issues mentioned above: https://apply.interfolio.com/108050

Response 1543

Perspectives on the postdoc roles and responsibilities

Advanced training toward an independent research career, regardless of sector.

Fundamental issues and challenges

NIH budgets. Grant budget caps do not allow us to pay anyone-student, postdoc, staff, or faculty-commensurate with industry. NIH policy to carve out funding for ECR/ESI applicants would have been a sensible approach to a short term problem, but over a generation it has instead created a larger PI pool that has decreased ability to recruit and retain talent in the public sector and consequently spread the same dollars over more labs, with less ability to pay postdocs enough to stay with public research at least through a typical training period. Other NIH policies exacerbate a tournament economy, with attendant path-dependent success rates such that we have very large research groups (often inefficient with respect to the last-chosen trainee, resulting in trainee disengagement while rewarding the PI) and very small groups (often struggling to maintain critical mass of personnel and equipment).

Existing NIH policies, programs, or resources

1) Index salaries/stipends supported by F, R, or T series awards. (New college graduates in most STEM fields make more than a third-year postdoc. That isn't right.)
2) Expand K99/R00 series as a pathway with sustained support. Anecdotally, this seems more productive than expanding ECR funding at first R01 only to have them fail at renewal.

Proven or promising external resources or approaches

No response

Response 1544

Perspectives on the postdoc roles and responsibilities

A postdoctoral position is a role for a trainee to work independently using skills from graduate school and gain further experience and build a research portfolio for their next career step. Ideally, a postdoctoral position will match an individuals career goals; the responsibilities and research should fit well with their next desired position. If a PhD is about learning how to think as a scientist and perform all parts of the research process then a postdoc is about becoming the scientist you want to be through practical experience.

Fundamental issues and challenges

I think many individuals view a postdoc as a waste of time unless you want to be a primary investigator, and many think that becoming a PI is not worth ultimately worth it. In the end they can get an excellent job right out of graduate school doing good science without doing a postdoc. Additionally, working in pharmaceuticals or biotech is viewed as better experience for future non-academic jobs than a postdoc. In my personal view, I want to do a postdoc because I like the academic environment, even though I am not certain about becoming an academic PI. I want to develop my skills in new subject matter and gain more perspective. A personal hold up is I have seen how lab dynamics are crucial and finding the right postdoc for my research, career goals, and personal goals seems incredibly challenging.

Existing NIH policies, programs, or resources

I am not particularly fluent in this area. I found the rotation year as a new graduate student to be incredibly helpful for selecting a lab to do my PhD in. Creating opportunities to connect with other labs and perhaps have PhD students experience other labs (maybe "intern") would be valuable for identifying future labs to work in.

Proven or promising external resources or approaches

No response

Response 1545

Perspectives on the postdoc roles and responsibilities

The postdoctoral position is an additional training position after graduate school to build skills and develop a scientific project to launch an independent research group. While technically still training, postdocs are highly skilled scientists whose work drives research output, and postdocs are often involved in mentoring as well.

Fundamental issues and challenges

Two things come to mind:

1. the uncertainty of academic path/opportunities after postdoc (will I be able to get a tenure track academic job?) and
2. the salary (can I support myself and my family?).

Existing NIH policies, programs, or resources

The NIH postdoctoral fellow pay scale sets the standard for postdoc pay (as an NIH funded IRACDA fellow, it directly sets my salary). To improve the postdoc training ecosystem and retention in academic research,

salaries need to go up, probably everywhere but definitely in high cost of living areas. I can only do this job (and it is job—despite the fact that it is also a training position) because my spouse (also a post doc in academic science) and I are DINKs—double income no kids. We also don't have other family members to support, and were lucky to have our parents pay for college. Basically, we can only do this because of immense financial privilege and no other obligations. This isn't equitable—the system is selecting for people with certain privileges, in direct conflict with the supposed goal to increase diversity in academic science.

Proven or promising external resources or approaches

No response

Response 1546

Perspectives on the postdoc roles and responsibilities

My perspective on the role of a postdoc is to be a final stage trainee to become an independent investigator. A postdoc should be driven and able to work independently at a skill level beyond a graduate student, thus should have the prerequisite skills to interpret data and design experiments under guidance of an established faculty mentor. Further, a postdoc should be able to communicate research needs and discoveries to grant providers and the community at large.

Fundamental issues and challenges

There is absolutely zero financial incentive to become a postdoc. A grad student is at least fighting for a degree. What do postdocs get in the end? Companies can train good scientists just as well and pay better to do it. Despite holding a terminal degree and being capable of highly skilled labor, I am paid less than I could have made by entering the workforce immediately after undergrad. I will likely not be able to own a house until I'm near my 40s. The mere mention that I wish to stay in academia is met with pity from friends who chose industry. Simply put, my lab is lucky I want to be faculty mentor one day.

A good mentor is extremely hard to find. I got lucky with my current position, but I've seen very clearly that not all PIs value their postdocs. Unfortunately a good scientist is not always a good mentor.

Quality of life is pretty low for postdocs who lack a spouse, significant other, etc. Single postdocs can barely set aside savings, nor have free time to do housework. Recreation time is low. Morale is low. A man in his 30s should not have to have a roommate.

Existing NIH policies, programs, or resources

I do not know. The NIH is a nebulous agency to me hidden behind walls of bureaucracy. Maybe it's dependence on the NIH that is the problem. Universities should probably be valuing and supporting their faculty research environments far more than a federal agency.

Proven or promising external resources or approaches

No response

Response 1547

Perspectives on the postdoc roles and responsibilities

Postdocs are researchers in the lab, working on their own research project and usually mentoring graduate/undergraduate students on a team.

Fundamental issues and challenges

I am unfamiliar with issues faced by postdocs

Existing NIH policies, programs, or resources

Unknown

Proven or promising external resources or approaches

Unknown

Response 1548

Perspectives on the postdoc roles and responsibilities

A postdoc is a skilled researcher who has intentionally chosen to undergo further specialized training for the purpose of attaining some higher-status position. Although this higher-status position does not have to be a tenure-track faculty position, it usually is. Because of these aspirations, postdoc positions are by definition transitory, in contrast to a research scientist who is a skilled researcher that intends to stay at the same location.

Fundamental issues and challenges

No response

Existing NIH policies, programs, or resources

- Expand the modular R01 to be at least $500,000, and preferably higher. This will reduce the amount of time faculty have to spend writing grants and free up more time for science.
- Put explicit minimum salaries on the R01 and other grants that are more in-line with the skills being employed, e.g. $80k-$120k for postdocs depending on COL.
- Reduce the amount of work that professors have to do! Less paperwork for grants, hiring, etc. Whenever possible, let submissions contain only a minimal amount of information initially, with the full grant only being submitted once the research idea is chosen
- Put limits on the number of postdocs that a lab can hire and direct labs to hire research staff instead. Why are we training so many postdocs if there are not nearly enough faculty positions for them?
- Start a publicly funded, NIH-led series of journals, where papers are initially screened by reviewers and then review happens in the open post-publication. This will reduce wasted time and costs spent at a journal and increase the ability of the NIH to reward good science, e.g. by forcing submissions to make all data open source, and by rewarding reviewers directly.

Proven or promising external resources or approaches

Increased pay, more tangible rewards, and more certainty about career paths tend to make people happier.

Response 1549

Perspectives on the postdoc roles and responsibilities

My view is a fairly traditional one, i.e. that an academic postdoc is an opportunity for advanced training that provides a springboard for someone with a Ph.D. to the next stage of their career, whether that is in the commercial sector, academia, public policy, etc. In my opinion, a postdoc has been (I am trying to understand whether it still is) a critical opportunity for someone to select an experience that is tailored for their next steps, after they have achieved the scientific maturity and knowledge to be able to narrow down what they want their future to look like.

Fundamental issues and challenges

There are four fundamental challenges in my mind, which are interrelated and which reduce the pool of highly qualified postdoc candidates:

1. Students no longer accept that a post-doctoral position is necessary to achieve their career goals;
2. Trainees are obsessed with "work-life" balance and do not feel they can achieve this in an academic postdoc;
3. Stipends/salaries are too low to support the life style that trainees desire and companies are raiding academic research labs, offering twice (or more) the salaries that we can provide in academia;
4. PDs (and Ph.Ds for that matter) are taking too long in part because it is getting more and more difficult to publish impactful stories in the best journals as expectations have increased so much.

Things have been changing for some time, but the ability to recruit postdocs has dropped precipitously since the pandemic. Raising salaries has its own downsides of course, as the higher the salaries, the fewer

people we have to do research in our labs. This is already happening with the unionization of students and PDs at many institutions. The model of how we do research in academia is going to have to change.

Existing NIH policies, programs, or resources

As a T32 director I have always been concerned that reviewers of our training programs are behind the times w/ respect to how they evaluate programmatic offerings. Current trainees desire career guidance and activities that are almost exclusively non-academic and encompass speakers and workshops that include careers that may not be (I fear) received well by reviewers. If NIH were to embrace career development more broadly and encourage T32 directors (by educating study section reviewers) to provide opportunities for postdocs to develop networks and career paths of all sorts, the trainees may see the academic postdoc experience as adding more value to their career progression. They may not go into academic faculty positions, but they may still choose to do a postdoc and then go on to productive careers in the commercial sector, government, etc. In addition, it is (mostly) not possible to support international trainees through traditional NIH funding (training grant/fellowship) mechanisms and many foreign trainees no longer see us as a place they want to come anyway. If NIH were to help increase the pool of qualified PDs by supporting international trainees, that would be helpful. NIH could also expand mechanisms that support more permanent research scientist positions in academia. NIH has experimented with this sort of funding mechanism, and if this path were expanded, trainees may see that there is a more permanent position possible following a short PD training period. There is also a cohort of postdoctoral fellows interested in jobs at smaller teaching institutions that also have a research component (running a research lab with undergraduates). Encouraging trainees on this path could be helpful, as those folks will be mentoring future researchers at these small liberal arts colleges.

Proven or promising external resources or approaches

Most institutions have offices of postdoctoral affairs that provide great programs for postdocs, and national societies also host retreats and career development programs and internships, but I don’t think I have anything specific/useful to add here that can’t be found online.

Response 1550

Perspectives on the postdoc roles and responsibilities

I view the postdoctoral position as an opportunity to enhance training while gaining independence as a scientist to pursue a new project (different than graduate school) and add mentoring opportunities to more junior trainees.

Fundamental issues and challenges

First and foremost is the financial issue. Many of my colleagues have skipped the postdoc or left their postdoc positions for industry that will pay up to three times the NIH level for an incoming postdoc. Many postdocs have family and other financial responsibilities that require a higher salary, in addition to rising inflation costs for food and housing. Other factors inhibiting recruitment of talented postdocs include toxic PIs during their graduate school experience and for many survivors of harassment they would rather leave academia than start again in a new institution that may also have possible toxic supervisors and work environments. Many trainees experienced long work hours and unrealistic work expectations in graduate school and therefore leave academia and do not complete postdoctoral training to escape these toxic expectations.

Existing NIH policies, programs, or resources

I am in support of any NIH grants that require postdoctoral formal training and mentorship by supervisors/principal investigators. Additionally, as an IRACDA fellow I am very happy with the professional development resources in this program and recommend additional funding for this award to be available to more institutions and more postdoctoral trainees.

Proven or promising external resources or approaches

I have attended conferences with trainee workshop sessions where some trainees have voiced that their institutions do not have a center postdoctoral training office. It is extremely challenging for a postdoc at one of these institutions to find resources and support when their home institutions does not recognize the postdoctoral trainees via a central office or program. Examples for such offices include an Office of

Postdoctoral Affairs, Postdoctoral training program, etc. This central office would be the administrative voice and connection between postdocs and postdoc resources within the institutions and larger science community (ex: National Postdoctoral Association).

Response 1551

Perspectives on the postdoc roles and responsibilities

A postdoctoral position allows the research to gain experience, socialize, and expand horizons, all of which are required to be an independent investigator.

Fundamental issues and challenges

Major Issue:

Less salary—I live [redacted for anonymity] and I pay more than 40% of my salary on house rent. The postdoctoral salary a way below if we compare it with industrial postdoctoral position.

Very less postdoctoral fellowship opportunities for immigrants.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1552

Perspectives on the postdoc roles and responsibilities

My time to showcase my earned skills and learn new technics in the field of interest, learn and advance ability to run my lab in the future. Increase number of senior future advisory connections and network.

Fundamental issues and challenges

Very low pay, absence of yearly bonuses, no job security due to short term contracts, on a grant being pushed to shift to Postdoctoral Fellow loosing benefits and doing taxes as independent contractor are stressful and unfair destructions in a postdoc life! Lack of postdoctoral NIH programs for international scientist even after joining Lab at US university, most existing would require permanent residency which takes years to get, as most international postdocs are hired on exchange visa originally. Transition NIH grants like K99 and R22 have inappropriately short time limits, good risky ground research project that are good enough for internarial postdoc to be competitive for future do not take less than 3 years especially for animal research. not all PIs will allow to take in Lab research as your idea that will take longer than just 3 years to fully form!

Existing NIH policies, programs, or resources

Set appropriate postdoctoral pay, not just 100$ above hourly worker, its ridiculous! Promote postdocs to apply for grants by adding a small bonus upon receiving one and require university to treat us as proper employee on a grant and not as a random contractor! Science supposed to be borderless, if I'm competitive enough to work in one of the best US universities I should have chance to compete for NIH training support as rest of ppl here, at least add grants for international postdocs or drop citizenship requirements at least for some! Increase years to apply for transition grants 5-6 year to give a chance to mature ideas and not to trap us out of science just because we did longer project! More grant opportunities for senior postdoc in the lab to actually start a branched independent research project , aka K99 without R00, to help postdocs develop their own direction before job search.

Proven or promising external resources or approaches

Like SFARI BTI increase or remove maximal postdoc years for transitional grants. Setting better pay levels and proper contracts (2-3 years at least) and treatment as university employees and not just a contractor with no days off, will help keep postdocs for choosing the corporate world. Organize or sponsor development of postdoctoral training programs at the university for lab management, collaboration forming and job applications/search etc. as future independent PI, to prevent postdocs to be trapped in

the lab and help to become part of university. Start asking postdocs to rate mentor and not only other way around, promote or require more than one mentor for the training.

Response 1553

Perspectives on the postdoc roles and responsibilities

The purpose of a postdoc should be to provide training to the postdoctoral scholar and to prepare them for a career in academia, by giving them mentored experiences in necessary research skills, including proposing and running studies, IRB, data management, data analysis, writing publications, grant writing, etc. Ideally, this is a mutually beneficial relationship between the postdoctoral scholar and their faculty mentors. However, too frequently, this is a relationship that mostly benefits the faculty, with little or no benefit (and sometimes harm) to the postdoctoral scholar. The power dynamics make this a precarious situation for postdocs, where it's difficult to prioritize their own career and growth.

Fundamental issues and challenges

It is not appealing to take a poorly paying postdoc when there are so few jobs in academic research and even the brightest scholars often don't make it, especially when there are viable alternatives that pay much more in industry. The additional sacrifices of moving for grad school, then again for a postdoc, then again for a faculty position, combined with the cutthroat nature of the academic job market make this untenable for many (or even most). Not to mention, postdocs are often designed to benefit faculty and not the postdoctoral scholar, meaning the postdoctoral scholar may spend their time on menial tasks that do not help them grow as a researcher or build their CV. Further, postdoctoral scholars are often overworked and at the mercy of (potentially abusive) faculty, with little to no recourse. Especially for prospective postdoctoral scholars with any type of family obligation (e.g., children, partner, caregiving duties to parents or extended family, monetary obligations to family or other dependents), this makes doing a postdoc difficult or impossible. Many can't afford the personal and financial sacrifice after 4+ years making poverty wages (and even taking out loans!) in graduate school. The system is set up to benefit the most privileged among us, and this harms individuals, communities, and science as a whole.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

The minimum salary needs to be increased, both for postdocs and graduate students (i.e., F31 and F32 minimum stipends). There need to be systems and structures in place to help postdocs who find themselves in abusive situations as well as formalized support and mentorship for postdocs who work with faculty who shirk their mentorship duties. There also needs to be more concerted effort to help students and postdocs who face structural barriers and inequities. There needs to be enforcement of maximum working hours.

Response 1554

Perspectives on the postdoc roles and responsibilities

Research training. Leadership training. Project development. Networking.

Fundamental issues and challenges

[Redacted for anonymity] systematically avoids the minimum postdoctoral salary by given a low population of postdoctoral scholars a different professional title without a minimum salary! It's my impression that this in particular applies to international scholars that are not paid by any US funding.

Existing NIH policies, programs, or resources

Treat postdocs well! Treat EVERYONE equally! Be inclusive! Be open and listen!

Proven or promising external resources or approaches

No response

Response 1555

Perspectives on the postdoc roles and responsibilities

My role is to earn additional experience running a lab, performing experiments, publishing, mentorship, and project management. I do all of these activities daily in addition to professional development and networking.

Fundamental issues and challenges

Financial limitations of salary and limitations to pay in general for outside services rendered. Without financial support, I am unable to stay a postdoc for more than a year or two. I am also limited in pursuing research interests of my own beyond that of my advisor which limits the amount of time I will stay a postdoc and my quality of life.

Existing NIH policies, programs, or resources

Overall, it is impossible to get credit for writing and managing large grant-funded projects as a postdoc as we cannot be listed as a co-PI on many grants despite this being our primary role. Not getting credit in this way is a major drawback to the position and also furthers the mistreatment of postdocs.

Proven or promising external resources or approaches

Providing options to get more one on one mentorship beyond our primary institutions, and guidance on how to access or where to access other resources to help career or professional development would be helpful.

Response 1556

Perspectives on the postdoc roles and responsibilities

Trained scientist that deepens its knowledge in a specific subfield in preparation for an independent position in academia. undertakes independent research and manages projects.

Fundamental issues and challenges

Severe lack of appropriate salary to offset cost of living. Increased interest in hiring life science doctors from other industries (biotech, consulting). Lack of opportunities after postdoctoral level (no added value on resume of pursuing a long postdoc if tenure track is not possible).

Existing NIH policies, programs, or resources

Increase the NIH postdoc minimum by 25%, include a cost of living adjustment for expensive cities (NYC, SF), pressure universities to lower fringe costs associated with postdocs hiring to principal investigators.

Proven or promising external resources or approaches

Many universities are increasing postdoc salary and it seem to have boosted postdoc interest. It is very obvious that salary is a big factor for people that may consider a postdoc but decide not to.

Response 1557

Perspectives on the postdoc roles and responsibilities

Vital to research and helping train grad students, postdocs are also well positioned to speak to the general public about what research they are doing. Postdocs represent more diverse backgrounds than PIs, are more aware (in general) of importance of social media and how to use it, and might be motivated to do public speaking.

Fundamental issues and challenges

Pay is still an issue, and outreach must be rewarded in some way (and have PI and departmental support).

Existing NIH policies, programs, or resources

More training on science communications, best practices, where to find good resources. Connect with regional SciComm groups and National Association of Science Writers. A lot of us give talks and trainings on science communications.

Proven or promising external resources or approaches

Working SciComm professionals could provide mentoring, but again, there needs to be some financial support to cover science writers' time and effort.

Response 1558

Perspectives on the postdoc roles and responsibilities

Roles:

1. Mainstay of advancing fundamental human scientific knowledge;
2. Communicator of cutting-edge research results to the general public;
3. Mentor of the next generation of scientists.

Responsibilities:

1. Independently manage high-impact research projects;
2. Envision, design, plan, conduct, and interpret experiments;
3. Reading literature;
4. Mentoring students and colleagues;
5. Writing grant applications.

Fundamental issues and challenges

Issues:

1) Glorification of high-impact papers and long working hours and simultaneous negligence of other valuable aspects of the postdoc's work (e.g., outreach, mentoring) as well as areas of life outside of work.

2) For international postdocs specifically:

a) lack of opportunities of fellowships and grants (most require permanent residency or citizenship of the US);

b) more challenging career prospects: it's much, much more difficult to get an industry job on a work visa than with permanent residency, but obtaining permanent residency is very costly (time and finance).

3) Much lower compensation (esp. salary) compared to a similar-level job in the industry. Rarely access to a decent retirement plan (vast majority of academic employers don't match contribution to 403b at all) only exacerbates that. This makes an international postdoc's life much harder combined with point 2) above (e.g., I'm in the processing of spending $7000 dollars to pay for me green card application and fees for a legal team who help construct the petition case. That's about as much as money I can save in a year! Not to mention the tremendous amount of energy that I poured into crafting the written materials).

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1559

Perspectives on the postdoc roles and responsibilities

A postdoc needs to be 50% do-what-you-want-to-advance-your-career (e.g., resumes, job applications, grants, publication writing) and 50% training for new skills (e.g., "on-the-job experience" with your PI).

Fundamental issues and challenges

Upon graduating with my PhD, I looked at several postdoc opportunities. However, the pay was not livable. Instead, I chose to work for a nonprofit where I can still publish academic articles in my area of specialization and get on-the-job training in more marketable skills (e.g., presentations to non-science audiences and true interdisciplinary work with advocacy/public policy professionals). If I wish to go back into academia as a professor, I plan to use this nonprofit experience and resulting publications as my "postdoc" experience. Of my friends who stayed in academia, most went straight into being professors without postdoc experience. Also, schools don't know whether to treat postdocs as students or as staff—Â so they end up getting none of the benefits and all of the downsides of both.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1560

Perspectives on the postdoc roles and responsibilities

A chance to gain independence and developed and refine a project/skills needed to establish and run an independent lab.

Fundamental issues and challenges

Childcare, perception as a women in stem, work-life balance, affordability of area, moving multiples times to different cities or states to gain the needed training not easy with spouse and children, access to resources to develop a project, being seen as a trainee but also a researcher, not having resources to help people with disabilities, out mentors not receiving proper mentorship training resulting in ab unsupportive environment

Existing NIH policies, programs, or resources

Expanding child care grant in training grants and adding an independent application to help cover childcare or spouse travel to conference. Having PIs take the resilient scientist program. Setting guidelines for hours worked under NIH funding. Adjusting grants based on area cost of living.

Proven or promising external resources or approaches

No response

Response 1561

Perspectives on the postdoc roles and responsibilities

I'm a former postdoc and have been an academic research administrator for the past ~20 years.

The first job of a postdoc is to discover something important. But their role should not simply be to produce data for the PI's next paper or grant proposal, which is unfortunately how many PIs see their postdocs. A postdoctoral appointment should be a career development position, and it should be a joint responsibility of the postdoc and their PI (and institution) to develop skills for a future career, whether academic or other. Technical skill in execution of experiments is necessary but not sufficient—postdocs should also learn to identify important problems in their field, plan research strategies to address those problems, develop professional networks independent of their PI, and (importantly) communicate effectively about their work. The late Patrick Winston (a prominent computer scientist at MIT) gave a talk to students in which he begins: "Your success in life will be determined largely by your ability to speak,

your ability to write, and the quality of your ideas—in that order." Unfortunately, many postdocs receive little or no training in the first two skills.

Of course many labs also need technical staff with specific skills whose job is to produce data under direct instruction from the PI—but those roles should be filled by staff scientists, not postdocs.

Fundamental issues and challenges

Our institution recently conducted a survey of postdocs, and unsurprisingly salary was the top concern. Our city is expensive, and the NIH scale does not reflect the rapidly rising cost of rent and other living expenses. Furthermore, many postdocs report being paid below the NIH scale, because PIs disregard prior years of experience to reduce salary costs. Although institutional policies discourage this, they are not always effective.

Our survey also revealed a surprising level of discontent at the quality of mentoring that postdocs receive. I believe this problem is exacerbated as the percentage of foreign postdocs increases (because low salaries and uncertain career prospects are unattractive to US citizens). PIs too often view foreign postdocs as cheap temporary labor. In addition to their vulnerable visa status, foreign postdocs' ability to self-advocate is sometimes limited by challenges of cultural integration and language fluency. Also there is an assumption (sometimes unspoken) that many of them will eventually return to their home countries, where their future career progression will not be the PI's responsibility.

Foreign postdocs are often reluctant to express concerns because they fear reprisals from their PI, on whom they depend for visa support and career progression. Institutional whistleblower policies are not sufficient to protect against these consequences, which can be subtle and are often invisible or unprovable. Thus, institutions will not discover the extent of postdocs' concerns unless they conduct anonymous surveys.

A fundamental problem is that individual PIs have too much power over their postdocs. In undergraduate education, students routinely evaluate their professors, and colleges compete to provide a valuable educational experience for their students. No similar reciprocal relationship exists for postdocs, and the power asymmetry leads to a system that is ripe for abuse.

Existing NIH policies, programs, or resources

Increase the postdoc salary scale, with adjustments for the wide differences in living costs between cities. This seems like a pressing issue, given that the cities with the greatest concentration of NIH funding also tend to be among the most expensive to live.

Issue guidance how to count previous years of experience when setting salaries, including experience in other countries, or in industry, or other academic disciplines.

I understand that resources are limited, and that higher salaries may mean that fewer postdocs can be supported. But it seems better to have fewer postdocs of high caliber, well-paid, happy and successful, rather than an excess of 'second-tier' candidates who are poorly paid and chronically discontented.

Include postdoc mentoring environment as an explicit review criterion, not just for training grants but for all grant applications that include postdoc salary support.

Require these applications to include a postdoc mentoring plan, which could address questions such as: Does the PI have a publicly visible mentorship statement? Are the lab's current and previous postdocs easily identifiable, and what is their professional visibility? Does the institute have a postdoc association, and what is the level of participation and activity? What % of postdocs completed an annual career conference? Does the institution have a formal mentoring system for postdocs, analogous to graduate thesis committees? What mechanisms exist for postdocs to convey their views and concerns to institutional leadership? What resources exist to support international postdocs and help with their cultural integration? Simply by requiring applicants to address these questions, NIH could provide a strong incentive for PIs and institutions to implement better policies toward their postdocs.

Consider awarding (small) grants to support postdoctoral associations, ideally with some level of independence from institutional control.

Proven or promising external resources or approaches

Some PIs have started to publish mentoring statements on their websites 'What you can expect from me, and what I will expect from you.' These websites sometimes also include names and contact info of current

and former lab members, explicitly encouraging future applicants to contact them to learn about the lab environment. NIH could collect such examples of best practice and promulgate them in its own mentoring guidelines.

I hear often from PIs that it is hard to recruit postdocs and expensive to advertise in journals or society websites. I learned recently of https://jobrxiv.org/ which seems like an interesting experiment that might be deserving of financial support from NIH. Advertising options are currently very fragmented, and all parties could benefit from an efficient low-cost online system for advertising/finding academic research positions.

Response 1562

Perspectives on the postdoc roles and responsibilities

I always have viewed postdocs as trainees who intend to join the research team to acquire training, learn to become independent, develop their own research direction and move forward to become independent PI. This position is meant to be occupied for 3-5 years at most. Unfortunately, nowadays postdocs are viewed as a cheap workforce that is hired for an indefinite amount of time to advance the prestige of the lab and support the growing careers of the PIs, who often forget how to run experiments and work at the bench and are reduced to the activities of the grant-writing machines. That happened because:

1. unhealthy views that a successful PI must have a large lab;
2. reduced and further reducing funding to support these large labs;
3. poor job security;
4. lack of benefits;
5. absence of work-family balance support

Fundamental issues and challenges

see above:

1. unhealthy views that a successful PI must have a large lab;
2. reduced and further reducing funding to support these large labs;
3. poor job security;
4. lack of benefits;
5. absence of work-family balance support;
6. declining prestige of the academic position.

These are the reasons why postdocs do not stay in academia and tend to join the industry workforce. Many of my younger colleagues who would be perfect junior PIs now are turning their backs to academia. Who would like to be a poorly appreciated workforce, working 12-14 hours/day for a $50k/year salary, with minimal benefits, no child support, especially in the coastal US cities, where the minimal rent of a 1-bedroom apartment begins at $3000? At the same time, the newly minted Ph.D. would receive ~ 140,000 in salary in an average California startup company. It is a no brainer fewer young trainees are attracted to academia

Existing NIH policies, programs, or resources

Funding! Make it competitive to the industry standards. Include family benefits and child support. Make it prestigious. Make quality over quantity, we may need fewer postdocs, but we need high-quality researchers. We do not need large labs, but smaller but highly productive labs. The PI should be a part of the team, working in the lab, mentoring, and training their team, not an advertising machine pitching their research at the international conferences and grant-writing mole, spending their time competing for NIH grants 24/7. We have been trained to run experiments, obtain new data, and make discoveries to advance our knowledge, and not to be grant-writing robots. We can do much more and much better than that. Also, fund the high-risk, high-reward approaches. NIH is notoriously known to grant R01s to research that is mundane, low risk, non-exciting, and has already been ~ 80% completed. Because this is, unfortunately, a recipe for a successful R01 application.

Proven or promising external resources or approaches

Private funding agencies that support early career investigators and trainees and make these jobs appealing and prestigious. Look at Pew Scholar Biomedical research fellows, GRS—seminars run by and for trainees. Also, I am not a big fan of postdoc unions—these organizations will eventually reduce postdoc-PI relationships to employee-employer one and will eliminate mentor-mentee relationships entirely.

Response 1563

Perspectives on the postdoc roles and responsibilities

Postdocs are the lifeblood of academic research. They are well-trained researchers capable of independently driving projects forward. Importantly, they are also in need of training in critical areas to become directors of larger research enterprises.

Fundamental issues and challenges

As highly educated, well-trained scientists, postdocs in academia are relatively underpaid. Increasing postdoc salary would help to retain the most talented doctoral students in research. That being said, increases in postdoc pay are passed on directly to individual investigators, whose budgets are already stretched to bursting.

Existing NIH policies, programs, or resources

Increasing the modular budget cap would significantly aid individual investigators in recruiting and retaining talented postdocs. Another tool could be the expansion of fellowships and training grants to support international postdocs. A cap on the indirect cost percentage recouped by institutions would free up dollars for direct research support.

Proven or promising external resources or approaches

postdoctoral offices at institutions help to centralize resources and provide stable training infrastructure that doesn’t rely on individual investigators to provide for all of the training needs facing postdocs.

Response 1564

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

No response

Existing NIH policies, programs, or resources

Postdoc salaries are too low. They need to be increased. However, this would leave grants with less money for research. The $500K/year limit for research grants have not been raised for decades. This limit has to be raised and postdoc salaries should be increased. In addition, these salaries should be calibrated by state—for example 50K postdoc salary in CA (San Franscisco, San Diego, LA) would buy much less than $50K salary in Mid West. This is not fair. Postdocs in CA spend over 50% of their salary on housing whereas for postdocs in Mid West housing would amount to 30% of salary. Needs correction by state and cost of leaving in that state toi make this equitalke.

Proven or promising external resources or approaches

No response

Response 1565

Perspectives on the postdoc roles and responsibilities

From my perspective, the postdoctoral position seems like a less than ideal career path for someone who has already completed their doctoral degree. In my opinion, it feels like a last resort for those who were unable to secure a job in their chosen industry. However, I also acknowledge that my personal views may not necessarily reflect the experiences of others who choose this path.

Despite my initial reservations, I have found my postdoctoral experience to be beneficial in terms of developing my research skills and providing me with opportunities for professional growth. Nonetheless, I feel that the recognition and support for postdocs are often insufficient. This is particularly worrisome considering that many postdocs work long hours and face financial difficulties due to the low pay and minimal benefits that come with their positions.

Furthermore, postdocs often lack job security, as their positions are temporary, and they may not have access to adequate mentorship and guidance. This can be especially challenging for those looking to establish a long-term career in academia. While postdoctoral training can be valuable in terms of building skills and experience, the current system needs significant improvements to better support postdocs and promote their success.

Fundamental issues and challenges

Postdoctoral training is crucial for individuals who want to pursue a career in academic research. However, the challenges that postdocs face can impact their quality of life. One of the significant obstacles is maintaining a healthy work-life balance. The demanding nature of academic research often forces postdocs to work long hours, leading to burnout and mental health issues. This is a concerning situation because postdocs with the same degree may have different lifestyles depending on whether they are academic postdocs or working in the industry. Low wages and minimal or no benefits offered by postdoc positions make it difficult for postdocs to cover their living expenses, such as housing, food, and healthcare. Some postdocs struggle to make ends meet and rely on university food pantries to fulfill their basic needs.

Most postdoc positions are temporary with little or no job security, leading to stress and anxiety among postdocs. The lack of mentorship and guidance negatively impacts their professional development and career growth. Postdocs work in isolated environments, which hinders their access to resources and support to advance in their careers. In some cases, labs are too large, making it impossible for one person to provide support to a team of 10 or more postdocs. To ensure equal opportunities for all postdocs to receive adequate support and mentorship, organizations like NIH should regulate the number of lab members a professor can hire.

Despite the valuable skills and experience that postdocs gain through their work, the highly competitive job market in academia limits their career advancement opportunities. Institutions should create more opportunities for career growth and advancement for postdocs. Hiring talented postdocs from outside the US could benefit institutions, but current visa and hiring processes make it challenging to hire foreign postdocs. Simplifying these processes could benefit postdocs and the institutions that employ them.

Existing NIH policies, programs, or resources

There are several existing policies, programs, and resources within NIH that could be improved or expanded to enhance the postdoctoral training ecosystem and academic research career pathways. One potential area for improvement is in the funding mechanisms available to postdocs. NIH could consider increasing the number of training grants available to institutions, which would provide more stable funding for postdocs and reduce the financial uncertainty that many face. Additionally, NIH could increase the stipend levels for postdocs to ensure that they are able to cover their living expenses and reduce financial stress.

Another area for improvement is in mentorship and career development resources. NIH could expand its existing mentorship programs to provide more comprehensive support to postdocs, including training for mentors and resources to help postdocs identify career paths and opportunities. Additionally, NIH could provide more funding for career development workshops and programs, such as the NIH K99/R00 grant program, which provides funding for postdocs to transition to independent research careers.

Finally, NIH could improve the job market for postdocs by encouraging institutions to provide more stable and secure job opportunities. This could include providing incentives for institutions to convert temporary postdoc positions into permanent staff positions or creating more postdoc-to-staff transition programs. By improving the postdoctoral training ecosystem and academic research career pathways, NIH can help ensure that the next generation of researchers is well-supported and able to make meaningful contributions to the scientific community.

Proven or promising external resources or approaches

There are several proven or promising external resources and approaches that could inform NIH's efforts to enhance the postdoctoral training ecosystem.

One such resource is the National Postdoctoral Association (NPA), which provides valuable resources and support to postdocs, including professional development opportunities, networking events, and access to a community of postdoctoral scholars. By partnering with the NPA and similar organizations, NIH could improve postdoctoral recruitment and training, as well as provide postdocs with more opportunities to connect with their peers and advance their careers.

Another promising approach is the implementation of mentorship and career development programs, such as the NIH's BEST (Broadening Experiences in Scientific Training) program. BEST provides postdocs with opportunities to explore different career paths, develop new skills, and receive mentorship from professionals in their field. By expanding such programs, NIH could enhance the working environment for postdocs and improve job satisfaction, ultimately leading to greater success in academic research career pathways.

Furthermore, NIH could also look to international models of postdoctoral training and career development. For example, in Germany, postdocs are often provided with more job security, benefits, and professional development opportunities than in the US. By studying and implementing successful international models, NIH could improve the postdoctoral training ecosystem and make it more attractive to talented individuals from around the world.

Response 1566

Perspectives on the postdoc roles and responsibilities

Postdocs are highly skilled professionals who have a PhD but seek to gain additional research experience. Roles and responsibilities are typically similar to PhD students but with increased expectations for performance with inferior support and a

Fundamental issues and challenges

Postdocs are not 'trainees'—they are highly trained professionals who have obtained the highest degree in their field, a doctorate, and are paid what is typically not a livable wage, at an age when there is increasing urgency to purchase a home, have a family, and save for their future.

In addition to all of this, faculty are often poor mentors to postdocs and there is essentially no accountability for poor faculty behavior.

Existing NIH policies, programs, or resources

Pay postdocs more money, increase automatically each year with inflation or at least increase every 3-5 years with inflation.

Proven or promising external resources or approaches

No response

Response 1567

Perspectives on the postdoc roles and responsibilities

The academic postdoc is a time to develop additional skills for eventual group leadership positions or for transitioning from one's phd field to a slightly related field. For many positions away from academia, a postdoc is not necessary. Postdocs are relied on for keeping American labs running smoothly, often mentoring graduate students and running projects.

Fundamental issues and challenges

The postdoctoral pay in the US does not enable a single person in their late 20s/30s to have the quality of life/standard of living that such an advanced degree and stage of life should afford, in my opinion. I could have taken my 4 year BS degree and received a higher salary. This is understandable in graduate school when tuition and fees are covered, but a postdoctoral degree is often 100% research, a highly specialized job, that should be paid accordingly. This is particularly true in labs where the pressure to achieve has

postdocs working 60 hour weeks. The inadequate salary is a massive hindrance in the large cities where many competitive postdoctoral positions are offered (e.g. Boston) and the cost of living, especially housing, is particularly high. This is also a primetime for children, and childcare expenses are so high and rarely subsidized. Ultimately, a postdoc needs a partner with a competitive salary or generational wealth to support the family. Sometimes persons with competitively awarded fellowships actually receive less support due to eligibility issues for other types of assistance.

Existing NIH policies, programs, or resources

People often delay parenthood during graduate school and postdoctoral training. Many private companies support women and men in their family planning by covering egg freezing, and I know this would have made a difference to me in recruitment to a US postdoctoral position. More comprehensive and adequate funding of childcare costs (as above) would be helpful. Postdocs who also have to start paying on students loans after graduate school may particularly feel the budget crunch. More support for health insurance costs would also be advantageous, this was well covered in graduate school and made the stipend livable.

Proven or promising external resources or approaches

No response

Response 1568

Perspectives on the postdoc roles and responsibilities

It is an opportunity for further training of a more independent nature after earning a doctoral degree.

Fundamental issues and challenges

Pay, benefits, and the short term nature of the positions.

Existing NIH policies, programs, or resources

There should be more NIH support both in base pay and benefits like parental leave.

Proven or promising external resources or approaches

Money, it is extremely difficult to live on a post doc salary in the majority of America. NIH could also offer specific programs for postdocs interested in their next steps. Workshops on faculty applications, industry transition, etc.

Response 1569

Perspectives on the postdoc roles and responsibilities

I don’t see any use in a post-doc.

Fundamental issues and challenges

I was fortunate to do a post-doc in a top lab and was able to obtain multiple funding sources (Damon Runyon, NIH). The main problem is that a post-doc simply isn’t useful. If going into industry, a post-doc is a huge opportunity cost (3-5 years of prime working time), and hiring managers generally do not count the experience—i.e. your experience level is zero if coming from a masters, PHD, post-doc, professor etc. The time is much better spent gaining actual experience beyond academic research and getting into a career path as soon as possible.

An example I saw recently were two professors, one assistent, one full, go into industry only as entry-level scientists. Academic experience simply isn’t valued past a certain threshold. If you are a true expert in a field, those cases are certainly different, but few and far in between.

As for QOL, it was generally good and I enjoyed the experience. Pay is certainly low, and was hard with kids etc. Again my only regret was not starting my actual career after my PhD. Basically I did what I thought was good work, published etc, but just no one values the experience.

Existing NIH policies, programs, or resources

Make more actual career paths for academic scientists. There are a lot of people that enjoy the work. No one wants to be paid 50K in an expensive city and delay starting families etc though.

Proven or promising external resources or approaches

NA, again a post-doc is not useful. Need real career paths.

Response 1570

Perspectives on the postdoc roles and responsibilities

Postdoctoral researchers are highly-trained and highly-specialized researchers. At a minimum, theu have some 8 years of higher education behind their backs. This position should be intended to:

1) Further their professional development: Ph.D. programs are very specific and result in specialists formation. By means of one or several postdocs, those researchers can be exposed to a wider range of science to further their views, which in turn will help them succeed in the long run.
2) Be competitive in nature: one thing we have learnt in recent years is, there are way too many Ph.Ds. graduating. Academia cannot keep up with the number of positions required, which in turn drives compensation for those down, and dilutes the effort it took to get where they are.
3) Be a launchpad to their senior careers. Postdoctoral research is surrounded by uncertainty. When will funding end? What will I do next? Some institutions succeed in talent retention, but most don't, and that fills postdoctoral research with anxiety, high-turnover, etc.

Fundamental issues and challenges

1) Compensation: The COVID-19 pandemic has showed us how poorly compensated most scientists are, including postdoctoral researchers. Although the NIH has done an stellar job in recent years in increasing fair compensation, it is still far from ideal.
2) Career trajectories: Postdoctoral positions should be launchpads, not landing ones. As it sits right now, a postdoctoral researcher may spend several months applying to positions that are more-or-less related to their graduate training. In some cases they will succeed in finding a role that is a continuation of their academic progression, where they can expand on it. But most won't, and will be tied to a laboratory where they are regarded as highly-qualified technicians, which they are not. Even when they succeed in finding the correct laboratory, many things can go wrong. Bad mentorship, poor colleagues, high competition among team-members, etc. Some of the issues are in the institutional domain, but others can be tackled from a systemic point of view.
3) Work-life-balance. Academia is one of the fields with the poirest work-life-balance out there, with postdoctoral-scientists being one of the groups that has it worse. With long work-hours and extra days of work, postdoctoral researchers who are most likely in their late 20s to early 30s have it hard to create and maintain families, this in addition to the poor compensation results in really bad quality of life.

Existing NIH policies, programs, or resources

1) A complete redesign of the postdoctoral support is needed, and further into researxh programs and policies. From how many postdoctoral researchers are allowed per grant to how many NIH-funded grants are allowes per investigator, NIH policy should be rethinked with the objective of quality science:
2) Limit overfunding: it may appear that the more funding a laboratory has, the higher the changes of misconduct. With increased funding there are increased number of personnel to supervise, data to keep track of, etc. Limiting the number of projects an investigator can have will allow for better oversight of the projects and personnel, production of higher quality science, and postdocs will benefit from more focused mentoring.
3) Create early to mid career funding. Some programs like the F99/K00 transition award offer excellent opportunities for growth, but their support is only limited to the training stage of their careers. A F99/K00/R21 program (for example) will offer a longer path for career development into the early-stage researcher stage.
4) Offer more support for alien postdoctoral researchers. Many postdoctoral researchers are not US residents, but they have long careers here. Most NIH programs require residence or cityzenship, limiting access to a large proportion of postdoctoral researchers to funding that would advance their careers, and presenting an unfair advantage to some others.
5) Related to 1, reduce the number of grants offered, but increase the support on those, especially for high-quality personnel.
6) Limit number of personnel per grant.
7) Offer personnel-only grants.
8) Offer mandatory training for supervisory positions on NIH-funded grants to ensure proper mentorship.

Proven or promising external resources or approaches

No response

Response 1571

Perspectives on the postdoc roles and responsibilities

The postdoctoral position allows for additional training beyond the scope of the Ph.D. thesis. It is usually in the best interests of the trainee to choose a field distinct from their Ph.D. training in order to gain a wide breadth of expertise and develop an appreciation of many active areas of scientific investigation. The postdoc is expected to leverage the experience gained by executing the scientific method during their thesis.

Fundamental issues and challenges

The current framework for postdoc training is actively and effectively pushing our most ambitious postdocs to private industry. A postdoc that nearly misses the recommended milestones is faced with the reality that they will never be given the opportunity to be a tenured faculty member at a research institution. This is true regardless of whether their later years are veritably more productive. That previously vicarious type-A research leader fueled by grandeur ambitions of running their own lab is now sidelined to a career path with very few opportunities for advancement. Their ambitions were futile and will have to adapt themselves to be complacent to put in their 9 am-5 pm to maintain their employment and vie for a raise that barely outpaces inflation. This realization precipitously drops their level of productivity and this reality is true for the vast majority of postdocs, which produce the bulk of the scientific discoveries. To reiterate, the majority of science is conducted by individuals who have been passed over by promotion because they narrowly missed the recommended milestones. It is no wonder, that our most ambitious researchers choose to leave publicly funded research institutions to pursue a career in the private industry. A person would not need to visit very many labs to find a highly intelligent individual that is more than qualified to run their own lab, but has been sidelined and is now begrudgingly content with a paycheck because they know that working harder will not open any windows of opportunities. Many talented, driven scientists miss the milestones due to starting a family or because, as a minority, they did not have socioeconomic support. It is no wonder there is little diversity in science faculty.

Existing NIH policies, programs, or resources

First, eliminate the time restrictions on K99 and other laboratory starter grants. These are intended to catapult scientific prodigies, but instead privilege individuals who were fortunate enough to receive an abundance of socioeconomic support and mentorship prior to receiving the K99. In addition, these time restrictions are counterproductive, the most talented postdocs are usually given more challenging projects that yield more impactful research with longer upfront time investment. Thus, the industry's most talented are being passed over and those opportunities are often handed to individuals who encountered fewer adversities in their training. Also, time limits stifle productivity, once the last deadline is passed, the postdoc realizes the doors of opportunity have closed on them and so ambition, then, becomes fruitless. Second, provide real incentives for postdocs to submit grants. Similar to faculty, a postdoc should receive a stipend boost when a grant is accepted. Otherwise, there is no actual, real, immediate benefit to submitting a grant. It is absurd that faculty are financially rewarded for funded grants, but not postdocs. Lastly, raises should be mandatory or more structured. These raises encourage postdocs to keep their positions at academic institutions. At the very least, these raises should outpace inflation. I have been told that most principal investigators neglect to provide annual salary increases to their postdocs, a service that even the most neglectful employers provide.

Proven or promising external resources or approaches

The best resources are those that advance the career of the postdoc. Even though the vast majority of postdocs will never manage their own lab because that opportunity is taken from them a few years after their career has begun, many postdocs desire professional advancements. Therefore, any service intended to foster career advancement is welcomed. For example, as a postdoc gets older, their work is seen as an indicator that they are a great bench worker rather than an indicator of a great principal investigator. Encouraging departments to have colloquiums for postdocs to speak would show the other faculty in the department the postdoc's true potential. The lack of these speaking engagements communicates to the postdoc that the department is not interested in their achievements unless it benefits their mentor. Training courses in grant writing, teaching, time management, and data analysis are welcomed and appreciated. Our institution provides these training classes and also plans many networking socials.

Response 1572

Perspectives on the postdoc roles and responsibilities

The postdoc's role is primarily to participate in research projects. Some of these projects will be relatively independent, others will be part of larger team science undertakings, and still others will involve explicit training of the postdoc by either their PI or others. Postdocs mentor graduate students and participate in both the local and wider academic community by giving talks, serving on committees, founding and participating in various initiatives related to the academy, and so on.

While postdocs do often learn new skills as part of their position, I do not think it's correct to view it primarily as a training position. This masks that postdocs often have significant independence, often already have a significant and highly developed repertoire of skills, and often spend a significant portion of their time acting in a managerial role.

Fundamental issues and challenges

From many perspectives, the postdoc is the worst option for employment for a person with a PhD. The pay is often worse than what is possible in industry, the work hours are often longer, the prospects for future advancement are often more bleak, the employment benefits are often worse (retirement, healthcare, etc.). None of the positive reasons for doing a postdoc come from the material conditions of the position. This presents an obstacle to recruitment, retention, and quality of life. These obstacles are also an issue of justice: since people with material security will be more likely to go on to postdocs, and this material security intersects with class, race, and gender.

Existing NIH policies, programs, or resources

One significant step the NIH could take would be to increase the minimum salaries, as well as ideally tie them to the cost of living in the area of the postdoc (and to increase with that cost of living).

Proven or promising external resources or approaches

Postdoc unions at public and private institutions provide probably the most definitive information about what postdocs feel that they need for better lives. The NIH can follow developments in unionization, contract demands, and contract achievements to guide their own programs. In my own union, salaries are important, along with better support for postdocs with childre, better health insurance, and better processes for bullying and harassment. The NIH could make positive interventions in all of these things.

Looking at unionization efforts will also underline that many of the concerns that postdocs have are material.

I also personally believe that more explicit NIH support for longer term research scientist positions can help evolve the postdoc into a more stable category of employment.

Response 1573

Perspectives on the postdoc roles and responsibilities

Postdoc is a temporary position hired by PIs to conduct mostly independent work with minimum cost both financial and advisory timewise to the PI.

Fundamental issues and challenges

Postdoc is a temporary position so the experiences could vary a lot depending on the hiring PI. Also postdocs are hired at PI's funding status and needs of PI's individual project. There is no guidelines from NIH on the the balance between postdoc hired and real demand of academic positions. It is not hard math, a continuedly funded PI could works from his/her 30s until 60-70s, plenty of postdocs have been hired during PI's career and only one could replace the position available when he/she retires. Academic jobs are not known for fast expanding. The system might seem to be beneficial to PIs but in the long run it is not competitive to attract best people to science.

Existing NIH policies, programs, or resources

Postdoc should not be a training position, These are already highly trained people. The current academic research pathway definitely needs to make more room for people between graduate students and PIs.

Proven or promising external resources or approaches

It will be good if NIH has guidelines/rules on how many postdoc a PI can hire with each type grant. Maybe adopting some measures from the medical doctor recruiting, training and career pathways.

Response 1574

Perspectives on the postdoc roles and responsibilities

A postdoc should should lead novel research, making use of the existing resources of an established lab to drive their own research forward to a point where they can obtain a faculty position and funding to start a lab themselves.

Fundamental issues and challenges

Post doc positions offer a low level of pay for a professional position with 5-10 years of prior experience.

Academically, post docs are seen as only possessing minimal training in need of more, not as proficient experts in their field.

Post-doctoral academia offers little job security. It is difficult for post docs to get tenure-track research faculty positions, and there is little incentive to do a post doc if desiring a career outside academia.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1575

Perspectives on the postdoc roles and responsibilities

1. An opportunity to learn technical skills
2. Mentor
3. Practice grant and manuscript writing
4. Get involved in service

Fundamental issues and challenges

1. Low payscale for tarinees
2. Unaffordable childcare/housing
3. Lack of uncertainty in terms of being able to sucessfully land a faculty position
4. Lack of mentorship
5. Mentors unwilling to support grant applications
6. Unwilling to let postdocs take their projects with them

Existing NIH policies, programs, or resources

1. Faster dissemination of information
2. Timely response from officials to inqueries
3. More guidance/mentorship role from the NIH when navigating academic journey

Proven or promising external resources or approaches

No response

Response 1576

Perspectives on the postdoc roles and responsibilities

Postdoctoral fellowships are a temporary (1-3 year) transitional period for graduate scientists to further develop their administrative and technical skills necessary to either independently run an academic lab or move to industrial positions. Postdocs are great ways to PIs to generate data and hypotheses for the lab, but have additional roles that should be supported more by the NIH. Postdocs are responsible for assisting the PI more directly with grant securing, paper submission, project development, training of graduate students, and developing their independent academic roles within an institution/broader scientific community in order to build their reputations.

Fundamental issues and challenges

On a direct scale, MONEY. Postdoctoral fellows are often in their late 20s and early 30s, beginning new stage of personal life. Graduate students cannot expect to transition into the next stage of their personal lives on less than 55k/year in areas with high-COL. PAY POSTDOCS MORE. NIH make it more attractive financially for science and we will continue to go into it! Increase grant payouts to scientists to support themselves.

At the institutional level, space for tenure-track professorship has stagnated at major academic facilities. This needs to be addressed by the NIH through incentives granted to academic institutions. Make it better for institutions to add tenured professors to their roster. There is no guarantee that post-docs will be able to transition to professorship at any institution, which makes the uncertainty of the low-paying “temporary status” of postdocs increasingly less desirable.

Existing NIH policies, programs, or resources

Money. Pay postdocs more to be able to support themselves.

Scientific advancement has also progressed much farther than in the past, so the requirements for publishing have become much more stringent. This puts pressure on postdocs to have to “publish more” in order to meet minimum requirements for success or transition out of postdoctoral positions into faculty spots. The NIH should address competency requirements for success to transition out of postdoctoral fellowships, such as “securing fundings” or other metrics that allow them to support themselves.

The big theme here is that postdocs are supposed to be like flowering seedlings in a greenhouse. The NIH needs to water them more and support them so they can transition out into the field and stand on their own. Postdocs will grow when they are supported and will want to continue to do good science when they are supported, financially and academically.

Proven or promising external resources or approaches

I mean to start, money. Just pay them more. That will make more people interested in going into a postdoctoral fellowship.

Response 1577

Perspectives on the postdoc roles and responsibilities

To me a postdoc position is supposed to provide specific training in the area of the mentor as well as support to pursue the postdoc's specific interests and career goals. Mentorship should include jointly creating a training plan and actually following the training play (making adjustments as appropriate and needed). The postdoc should not be expected to primarily perform research assistant tasks, but rather should receive hierarchical training/mentorship in supervising research assistants and how to effectively manage/run a research lab. While working on the mentor's research is an integral part of being a postdoc, postdocs should be allowed—and EXPECTED—to complete individual projects and collaborations that will grow their own areas of expertise. This should be supported by the mentor and not discouraged. Postdocs should have supplemental didactic training related to the research and data analyses being conducted and provided with professional development opportunities (e.g., funding for conference attendance and presentations, workshops, career exploration). Further, postdocs are often expected to pay out of pocket to attend trainings or conferences--again this is not sustainable as postdoc salaries barely cover the cost of living! I can't afford to attend conferences to gain training, networking, or other invaluable experiences without funding help because my salary barely covers my monthly expenses just to live in a metropolitan area where my postdoc is located.

Fundamental issues and challenges

Mentors often don't encourage or allow postdocs to pursue their own research to work towards their independence. They are expected to be solely devoted to the mentor's research at the expense of the postdoc's personal/professional growth. Mentors lack formal mentorship training making the postdoc experience negative and draining, causing burnout. Lack of support to pursue one's interests (e.g., applying for small grants for independent projects, allowing time to finish manuscripts from dissertations) makes staying in the postdoc environment something that I don't want to do. Due to lack of adequate mentorship (e.g., reluctance of the mentor to have formal weekly or biweekly lab meetings, lack of structured didactics) I am leaving research/academia for a private organization where mentorship and postdoc wellbeing is prioritized. For those not on T32s but funded by the mentor's grants there is lack of paid parental leave. This is an issue that i quite frankly a major reason why individuals leave postdocs. AND, often times faculty do not support their postdocs receiving paid parental leave because the mentor "needs them to do the work" rather than support the postdocs in developing skills for having a healthy work/home life. Postdocs are treated as cheap laborers rather than being trained for specialization. The pay is too low for our level of experience. Recent graduates from master's programs (e.g., Master of Social Work) often earn $55,000 to $60,000. Yet, postdocs despite their extra training and expertise make less than that. It is not sustainable for cost of living in most major cities and is very much a deterrent for pursuing a postdoc. Industry positions and postdocs will pay much more. Postdocs want to be compensated appropriately for their level of training and expertise.

Existing NIH policies, programs, or resources

Every faculty who is going to be a postdoc mentor or have trainees should be required to attend yearly mentorship training. Postdocs should be allowed and encouraged to complete evaluations of mentors each year to ensure that mentors are providing the training and services that are needed for postdocs to be successful. This should be mandatory for ALL faculty that has a postdoc at any institution that receives NIH funding, regardless of whether the postdoc is on a F32, T32, or funded by the mentor's grants. It should be a uniform policy that should be evaluated each year to ensure that postdoc training is at minimum adequate, fair, and protecting postdocs.

Proven or promising external resources or approaches

No response

Response 1578

Perspectives on the postdoc roles and responsibilities

As a postdoc my core responsibilities include conducting and publishing research, applying for grants, mentoring students, presenting at conferences, developing my own research program, building collaborations with colleagues online and offline, and keeping up with latest scientific developments. I view the position of postdoc as similar to the role of Assistant Professor, but with less focus on administrative and grant-writing tasks and higher focus on data generation, analysis and non-administrative scientific writing.

Fundamental issues and challenges

The fundamental challenge is low pay for postdocs, especially in high cost of living environments, combined with limited career perspectives and security within academia. While pay and career perspectives have stagnated, the bar for successful academic grant and job applications has been set higher and higher, as evidenced by the increasing length of postdocs.

Existing NIH policies, programs, or resources

As a non US citizen and non-permanent resident, I am not aware of NIH programs that could be useful to me.

Proven or promising external resources or approaches

Focus on fewer, better-paid postdoc positions, providing a clearer and more transparent path to faculty roles.

Response 1579

Perspectives on the postdoc roles and responsibilities

The main perspective is to get a permanent position in industry, thinking in a 3-5 plan, but not discarding the possibility to get a position as a PI or similar in the academic field

Fundamental issues and challenges

Low wage considering:

1. The years expending in training and study to obtain a PhD degree—Similar positions outside academia pays twice more
2. Increase cost of living

Visa restrictions obliges us submit ourselves to wait at least 5 years to get a job without worrying about visa sponsorship

Existing NIH policies, programs, or resources

More grant options directed to foreign postdocs

Proven or promising external resources or approaches

No response

Response 1580

Perspectives on the postdoc roles and responsibilities

Frankly, in an academic setting, postdocs carry the burden of the research activities although they were not part of the planning process. Recognition for the work we do has fallen short, but I am hopeful that change is coming.

Fundamental issues and challenges

The difference between the medical residents and fellows and postdoctoral researchers is in the type of work. However, there is very little difference between them other than salary. Both are trainees, supervised, long hours, and given increasing responsibilities with experience. Salaries do not change for postdocs as they gain experience when residents do. To improve retention, provide equivalent salaries:

https://www.cc.nih.gov/sites/nihinternet/files/internet-files/training/gme/Terms_Conditions.pdf

Existing NIH policies, programs, or resources

As a pending fellow, it was disheartening to learn that I will not have the same benefit as a university employee (aka postdocs not on NIH fellowships). The reason, the definition of "employee". NIH Fellows benefits are restrictive if not viewed as an employee of the university. Because of this discordant, it has produced dissatisfaction before I even begin. Contrary to popular benefits, not all benefits are created equal. So, let's expand the policy to allow employers to classify postdocs as employees—regardless of the funding source. On the financial backend—employers are reimbursed for providing benefits rather than allowing separate entities to handle it.

Proven or promising external resources or approaches

Continued collaboration with the NPA—they hear the voices of postdocs frequently.

Response 1581

Perspectives on the postdoc roles and responsibilities

I am in the field of social work, which often comes with a heavier teaching and service load that other disciplines. I know that fact discourages many social work academics from applying for post-doctoral training opportunities. Additionally, I am a woman with children and a disabled aging parent and juggling the commitment to my training with personal and professional responsibilities can be difficult.

Fundamental issues and challenges

I wonder if having the ability to commit 50% of time to a career development award would be beneficial in helping those with other professional and personal responsibilities feel that they can apply for a CDA and be successful.

Additionally, CDAs are seen as highly competitive and I was explicitly advised against applying for such an award (by someone who is now my mentor for my CDA). Perhaps the perception of the barriers to success reduce applications?

Finally, as a social worker who conducts services research—social work may be a field for new growth for training from the NIH. Many social worker researchers don't feel that it is an option for them —for the reasons stated above and because social work often feels that it has to fight for legitimacy and prestige amid other social science research disciplines--but in my view social workers (which emphasizes a professional background in practice settings prior to getting a doctorate) will be critical to advancing health and health services research. Our deep knowledge of practice and practice settings (which many other health services researchers do not have), a LONG history of considering social and structural determinants of health (social work basically invented the concept), and advanced methodological training and experience in stakeholder engaged and anti-oppressive approaches to research (social work also basically invented the concept of anti-oppressive research) are required to move health research forward.

Existing NIH policies, programs, or resources

See above.

Proven or promising external resources or approaches

No response

Response 1582

Perspectives on the postdoc roles and responsibilities

Postdocs (when present) generate the vast majority of the research that any given lab produces. They mentor undergraduate and early graduate students and establish protocols within the lab. They often take on responsibilities of lab managers when such a person is not explicitly employed in the lab.

Fundamental issues and challenges

Postdoc'ing, as it is currently set up is an underpaying, overworking, and highly precarious form of employment. The job prospects following postdocs, that are supposed to be appealing enough to entice PhD level people to make this sacrifice, hire at an incredibly low rate. All of this occuring during the time when people are thinking about or have already started families. Offering improved benefits (subsidized housing, subsidized child care, SIGNIFICANTLY higher wages) could offset this. Something should probably be done to address the rampant unreported overtime and borderline (or overt abuse) by PIs particularly towards international postdocs.

Existing NIH policies, programs, or resources

Easy—More fellowships attached to individuals that pay more.

Proven or promising external resources or approaches

No response

Response 1583

Perspectives on the postdoc roles and responsibilities

The academic postdoc serves the purpose of cheap labor for PIs and the associated institutional bureaucracies. This de facto wage slavery is compounded with threats and exploitation to any form of protest/dissent by the aggrieved, which reinforces the totalitarian tendencies of the modern university. The role and responsibility of the contemporary postdoc position is to serve capital interests. Everything else we are told (e.g. exciting career potentials, helping the world, bettering mankind, etc.) is a lie.

Fundamental issues and challenges

See above. Also, it's clear there are internal contradictions in the fundamentals of the current system that will cause the system to self-implode. This will be highlighted by declining recruitment, retention, and a severe deterioration in the quality of life of postdocs. The word choice of "trainee" highlights the extreme totalitarian hierarchy present in the current postdoc system, where indebted wage slave must report without dissent to their masters. So yeah, [redacted] NIH.

Existing NIH policies, programs, or resources

NIH needs to be eliminated. It does more harm than good for society. Once NIH is eliminated, we will be able to address the role of the university as an institution in society.

Proven or promising external resources or approaches

See above.

Response 1584

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

SALARY. Postdoc salaries are not competitive. Although NCI pays its fellows higher than average postdoc salary, the lack of benefits makes it not worth it.

The fact that NIH postdoctoral fellows don't have access to a 401K (and in the case of foreign fellows, we also are not allowed to open Roth IRAs since the first 2 years we are non-residents). The lack of unemployment benefits too.

LACK of CHILD SUPPORT. 12 week paid maternity leave is not enough for any woman to recover, or for spouses to support them. Most fellows are foreigners which means we don't have any family support in the USA. How are you supposed to leave a 12 week old baby in daycare?. Although NIH has daycare, I don't know of anyone who managed to get their kids in it. All child support is only elegible for employees, not fellows. The fact that we are fellows makes us inelegible to subtract daycare from our taxes (or to file jointly with our also foreign spouses).

J1 visa 2-year rule (212E)—needless to say this is a huge problem for foreign postdocs fellows who want to stay in the US. In my case I was not informed this would apply (this was my second J1 visa and in my previous one it didn't apply). If I would have known, I wouldn't have joined NIH as this has complicated my personal life.

Existing NIH policies, programs, or resources

Paid maternity/paternity leave increase. NIH should take a hard look at European Research centers and their policies.

Real access to NIH daycare or "grants" to cover part of daycare outside of campus.

Flexibly work environment.

Ability to work remotely from outside the US for foreign fellows in case of family emergency.

Increased stipend.

Proven or promising external resources or approaches

No response

Response 1585

Perspectives on the postdoc roles and responsibilities

Now that one has a PhD, the postdoctoral position is a time to learn new techniques and expand on the knowledge area into what one is interested in, and also learn more about biotech, pharma, policy, academia, etc. to transition to an independent position afterwards.

Fundamental issues and challenges

Most of the fundamental issues stem from short-term postdoctoral positions available (sometimes advertised as 1—or 2—year positions), no retirement plan, low pay after having very low pay during graduate school, and no long-term position without moving again. Postdocs are an asset to the research enterprise, and should have pay that is consistent with expertise and cost of living in the area.

Existing NIH policies, programs, or resources

"NIH minimum" pay stipends are often seen as the normal pay offered. Institutions' benefits often change when postdocs gain outside funding—this should be mandatory to require benefits. Grant funding mechanisms should provide enough in the budget to allocate for postdoc pay and benefits along with other lab personnel.

Proven or promising external resources or approaches

% Time allotments for training, expertise, courses

Benefits (health, dental, vision)

Pay = cost of living in area

Require mentors of fellows to have taken RCR or equivalent

Climate survey of institutions' programs

Allow funding mechanisms for not-independent long-term careers (research associate, research fellow, post-postdoc)

Response 1586

Perspectives on the postdoc roles and responsibilities

Postdocs are critical to the research mission but are next to impossible to find / hire.

Fundamental issues and challenges

the #1 issue is salary. We are in Boston MA and it is impossible to live in this city on the NRSA post doc scale. It needs to be increased

Existing NIH policies, programs, or resources

the NIH needs to fund higher salaries for post docs

Proven or promising external resources or approaches

No response

Response 1587

Perspectives on the postdoc roles and responsibilities

Postdocs are the ones driving academic research, with the technical knowhow to conduct experiments and the academic knowledge to drive their own projects. They are the ones that are training new lab members and mentoring graduate students. In addition, they are expected to be applying for grants, publishing manuscripts, and furthering their professional development in preparation for opening their own labs. PIs are exceptionally dependent on postdoctoral work for publications and grant applications.

Fundamental issues and challenges

Salary is the biggest one. If you compare postdoc salary to the comparable positions in industry, there is no contest. Postdocs have more technical training than almost anyone else in any career, and are still barely paid a livable wage. Even if post docs have a love of science, that's not enough to pay the bills, especially if they have a family to support or live in an area with a high cost of living (Boston, California, etc). After 5-7 years of low wages as a grad student, the majority of post docs don't have savings and are likely in their thirties with little to no opportunity to buy a house, save for retirement, pay off student loans, etc. and yet are still expected to work more hours than their counterparts in industry. There's also very little protection for trainees in academia, with the majority of oversight left to individual PIs, which can and does lead to exploitation of trainees. In short, paying postdocs what they are worth and giving them benefits (access to retirement accounts, maternity leave, etc) and putting systems in place to give trainees recourse against exploitation are good places to start, or we will continue to see the exodus of post docs to multiple industry options which offer these.

Existing NIH policies, programs, or resources

Currently, postdocs supported on a fellowship are not allowed to contribute to our school's 403b option, as they are considered to be on a "stipend", and therefore are not eligible to contribute to retirement. Meanwhile, their peers who are supported by their PI's grants are considered employees and therefore are allowed to contribute to their 403b. It's the same job title, and same compensation, the only difference is that the students on fellowships obtained their own NIH funding. It does not seem fair that they are being punished for that. In industry, they would have a 401K with matching. As someone in their thirties who has a PhD, they should absolutely be allowed to start saving for retirement. And they should be making enough that they can contribute to retirement while still being able to afford to live in the area where they are working.

Proven or promising external resources or approaches

All efforts to enhance the training ecosystem are all good ideas but will do very little without first raising postdoc salaries and increasing benefits. Postdoc positions are no longer the only option for graduating PhDs, and they are no longer competitive. Inflation is at an all time high, yet salaries have stalled. If you want postdocs to stay, then you need to pay them fair wages. This is the absolute biggest thing to do to improve postdoc recruitment and job satisfaction.

Response 1588

Perspectives on the postdoc roles and responsibilities

I was a federal postdoctoral fellow, working at the NIH and FDA. I was excited to gain more independence and authority as a postdoctoral fellow. In my experience postdoctoral fellows drive the work conducted in major research laboratories at both academic institutions and in the federal government. We did the day to day running of the lab, wrote papers, trained staff, and informed the PI about adjustments to protocols. It should have been the most stimulating time in my career but it was stressful and disappointing because of how postdoctoral fellows are paid in the federal government. It was hard to focus on my work while being reminded that if I became severely ill or didn't get a W2 job soon, I would either end up homeless or working until I died of old age.

Fundamental issues and challenges

I advise everyone who doesn't want to become a tenure-track faculty to get out as fast as possible because of the massive financial hit American postdoctoral fellows take. Despite being highly trained professionals, fellows are treated like students in a "temporary" training position. While my stipend was enough to live comfortably off of, I was penalized by the IRS and banks because of my status as a 1099-G paid fellow. For example, I did not "earn" any of my income meaning that my family couldn't receive childcare benefits. If anything happened to me, I had zero social security. I could not save for retirement either and had to put money into a spouses account under his name. We shouldn't have to be married to have retirement savings. Finally, my status almost prevented us from being eligible to purchase a home. First time homebuyer programs exclude 1099 income. This might be OK for someone in their early 20s but can becomes catastrophic for someone who has this form of income for 10-15 years, the time it takes to complete predoctoral training, a doctoral degree, and a postdoctoral fellowship these days.

Existing NIH policies, programs, or resources

The NIH needs to reconsider how fellows are paid so that they aren't financially penalized and ineligible for basic worker protections and benefits. The NIH needs to be more explicit when recruiting postdoctoral fellows so they understand the limitations of 1099-G income.

Proven or promising external resources or approaches

I have heard that in other countries, and in the past in the US, postdoctoral fellows are employees not "students". I have also heard that it depends on the type of funding the postdoctoral fellow receives. Graduate students and postdoctoral fellows would be more willing to stay in the lab driving American biomedical research if it weren't a financially irresponsible thing to do.

Response 1589

Perspectives on the postdoc roles and responsibilities

Independent project development and management, practicing independent thinking moreso than during PhD. I don't view it as necessary if not interested in academia as a career path

Fundamental issues and challenges

Low pay, no tangible end point, lack of work life balance, high amount of effort for not as much benefit if not going into academia

Existing NIH policies, programs, or resources

Fighting for grants and using grant funding as a metric of success is not conducible to personal and professional development. Career development workshops and courses seem beneficial

Proven or promising external resources or approaches

Higher base pay, more opportunities for funding, workshops for existing postdocs that focus on teaching ability, requirements for teaching programs for current postdocs

Response 1590

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

Considering all the hats that postdocs have to wear to be successful (outstanding lab work, teaching courses, mentoring, lab managing), we should be paid significantly more than the NIH minimum.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1591

Perspectives on the postdoc roles and responsibilities

A postdoc is an opportunity to further one's expertise within a field and prepare for a leadership role in academia (PI of a lab) or industry (expert in the field for consulting, or project management).

Fundamental issues and challenges

Money. Stop pretending there is any other issue. I just spent 5 years making less than minimum wage and now you want me to dedicate 1-5 more years doing more work for ~$30/hr. The NIH shows nothing but disrespect and lack of value for a person in a postdoc position by offering half the salary to what is earned in industry. "For the love of the job/science" is the biggest exploitation scam out there. We have 8% inflation, sky high rent (because $55k a year will never afford someone a house), increased food costs, and every company cutting corners at consumer expense to maximize profit but you're telling us we are "experts in the field" worth only twice minimum wage. The NIH has job postings for project manager positions requiring a bachelor's with pay ranging up to 100k but you're telling me a PhD is only worth half that? You're shooting yourselves in the foot and in the same breath asking what happened.

Existing NIH policies, programs, or resources

Pay people more. https://arxiv.org/pdf/2205.12892.pdf

Proven or promising external resources or approaches

Whatever you need to do to pay more.

Response 1592

Perspectives on the postdoc roles and responsibilities

A time to expand into a new skillset while working independently towards their own career—they help the lab solve a unique problem by bringing new ideas and techniques. They help disseminate information and as such are an apprentice, except they act to develop their own line of thinking.

Fundamental issues and challenges

US students have too much debt to take on the low salary

Academic careers look unappealing as funding is so hard to attain.

They are discouraged as even the most excellent students do not get F or K awards.

Industry offer good salaries that are perceived to be more stable *in terms of employment.

Overseas post-docs are great and abundant but if Indian/Chinese, visa issues are present and they are taxed at a uniquely high rate so their quality of life is poor

Existing NIH policies, programs, or resources

Training grants and Career development awards—make these smaller so you can give out more to provide that reassurance and encouragement for trainees not to give up and stay in academic careers

Increase stipends

Allow post-docs that have clear paths to US residency the opportunity to apply for standard K awards (currently only K99 allowed)—for example O-visa holders?

Proven or promising external resources or approaches

Perhaps a way like glassdoor.com so that post-docs can post information about institutions and their lab environments so toxic labs can be identified by people looking around. PIs of labs could be reviewed like physicians are! Institutions could be ranked on their support methods?

Response 1593

Perspectives on the postdoc roles and responsibilities

Postdoc SHOULD be a training position focused around completing the postdoc's skillset in order for them to obtain a long-term position that uses their scientific background. Unfortunately in practice, postdoc positions often function as a source of cheap highly-skilled labor for academic labs, where researchers can be hired for low salaries without any serious effort to provide meaningful training as there are no oversight structures such as graduate programs.

Fundamental issues and challenges

Postdoc training is only truly necessary for a faculty position, and the training path for a faculty position has become too demanding. Between PhD and postdoc, trainees are expected to spend about a decade of their prime earning years in a position that requires immense financial and personal sacrifice, without a strong guarantee of getting the desired faculty job in the end. Postdoc salaries are incredibly low for the training required (much lower than industry, and even intramural NIH postdoc salaries are much better). Benefits are inconsistent and typically poor, with most universities excluding postdocs from retirement benefits and often classifying postdocs funded by fellowships in a way that prevents them from paying into and thus qualifying for social security. The expectation to move cities between grad school, postdoc, and faculty positions comes at great personal cost to many: trainees wishing to have children must constantly recobble together a support network that can compensate for their terrible salary, trainees with partners face the choice of moving to extremely high cost of living cities where both can get a job but postdoc salary is a poverty wage, or moving to more remote locations where the partner will likely struggle to find good positions. Postdoc training seems roughly analogous to medical residency, which also pays poorly temporarily, with the key difference that medical residency programs are set up so that the residents are essentially guaranteed to readily obtain a well-paid job as an attending physician.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

As is stands, the financial sacrifices required to compete for an academic faculty position are so great that only individuals who come from highly economically priviliged backgrounds can pursue academic science seriously, as most people cannot afford to spend so much of their prime earning years in poorly-paid training positions that hold unclear prospects for obtaining faculty positions that pay well, but nowhere near well enough to compensate for the financial sacrifice incurred during training.

Response 1594

Perspectives on the postdoc roles and responsibilities

Postdoc is an intense training period where you should learn skills for a future independent career and achieve some accomplishments in your desired field that will open doors for future jobs. The postdoc should be responsible to understand, and articulate, exactly what they need / expect from this training period. They should expect support for those goals, drive themselves to rapidly achieve them, and then move on with their career.

Fundamental issues and challenges

1. PIs treating postdocs as graduate students—i.e. not giving them space to pursue independent directions, not giving them lead roles in developing stories or writing manuscripts and grants.
2. Lack of financial support for child care.
3. Lack of structured mentorship programs that prioritize progressing the postdoc's career over their mentor's career.
4. Mentoring experiences that are largely PI-postdoc. Postdocs should have a mentoring committee as a formal part of all their training to protect from undo influence from the PI.
5. Length of time needed to build a strong CV for academic jobs / overly long publishing timelines.

Existing NIH policies, programs, or resources

Raise postdoc minimum salary to 75K. This will mean fewer postdocs can be hired, but it will put pressure on graduate students to not treat postdoc as a default next step.

Proven or promising external resources or approaches

Have the NIH sponsor childcare at universities. Have it set up so sick kids can participate and parents aren't on call every time a kid throws up or runs a fever. Subsidize the complete cost of childcare such that the net income (after childcare expenses) to parent postdocs is the same as those without kids. Sponsor this through the University or require it from indirect costs that that it doesn't fall on the PI budgets.

Response 1595

Perspectives on the postdoc roles and responsibilities

My stereotypical view of being a post doc included drafting manuscripts and writing grants. However, my position at a public regional university has involved some of this, but has primarily focused on training and managing undergraduate research assistants. I never intended to take a postdoctoral position as I attended graduate school to become a professor at a small liberal arts institution and create a strong undergraduate research program (since research opportunities can be difficult to find at these institutions, making graduate school admissions difficult for students from them). Because my current position was advertised as geared towards mentoring undergraduate students, I decided to apply. I also had never attended or worked at a public regional, so was excited to explore this type of institution.

Fundamental issues and challenges

I believe many graduate students have the same perception of postdoc positions as my original stereotypical view--days spent writing manuscripts and grants. Along with this, they are believed only to be useful to those interested in an assistant professor position at an R1 institution. However, they know these opportunities are limited in the current academic job market. So, why seek out a postdoc position if the end goal is not possible? To help with recruitment, there need to be more broad postdoctoral opportunities, including those geared towards alt-ac and industry positions. In order to recruit specifically for retention in academic research, there needs to be a pipeline to tenure-track faculty lines. Graduate training also needs to be improved. For example, my PhD advisor never assisted me in learning how to apply for grants. I applied and received several internal grants and small external awards, but feel there is a large hole in my training. I am not prepared to apply to a job at an R1 institution, even if I wanted to do so. My quality of life as a postdoc seems quite good, but that is only because I make more at the NIH rate than I would as a tenure-track assistant professor at a small liberal arts school ($51,000/year). This discrepancy in base salary based on institution type is also a problem, since those postdocs who do not get a position at an R1 institution will be taking a pay cut at a smaller institution, normally in an undesirable location.

Existing NIH policies, programs, or resources

1. Use AI to target the NIH Guide TOC to subscribers research interests
2. Find a way to advertise NIH Grants Conference to ALL grad students in biomedical research (assist them in learning the NIH ecosystem early & incentivize this participation)
3. Expand opportunities for the full range of higher education institutions (can partnerships be developed between small liberal arts institutions and R1s so that researchers at smaller institutions have the necessary infrastructure to be awarded grants?)

Proven or promising external resources or approaches

Improving the ecosystem will involve improving graduate degree mentoring and improving the academic job market. Postdoc life is not divorced from these issues. However, postdoctoral positions could be better advertised. Many of these positions seem to only be advertised within specific niche scientific societies or transmitted through grad advisor's connections. There are the T32 mechanisms, but you have to have a graduate mentor who encourages or makes you aware of these opportunities early in your grad career. PIs also need to be held accountable for postdoc mentoring. The postdoc should weigh in on their mentoring as part of the faculty member's performance review. Currently, postdocs are in a weird place in many academic institutions. They have no place in shared governance and limited contact with those outside of their PIs' lab. This can be particularly isolating for postdocs at institutions with only one other postdoc. So, postdocs need some kind of specific support and networking assistance.

Response 1596

Perspectives on the postdoc roles and responsibilities

A postdoc position serves as additional training and as a preparation period for setting up the direction of a future lab.

Fundamental issues and challenges

I believe two major things that inhibit people from seeking post-docs. The first is the salary. Postdocs put in a lot of work for a minimal increase in salary after getting their PhD. The thought of going to a different type of position where the pay is much much higher is incredibly enticing after spending so many years financially struggling and now being faced with having to pay back any accumulated student loans. Relating to this, if people want to finally start having families after years of being a true "student", the low salaries are a huge detractor. Second, PIs seeking postdocs qualify their search by stating they are in need of "quality post-docs". This says to me, "I want a postdoc that requires zero training". The point of the postdoc in my mind is to continue learning new things.

Existing NIH policies, programs, or resources

Increased pay across the board. Funding for child care in funded fellowships/grants. Mentorship training for PIs wanting to hire postdocs.

Proven or promising external resources or approaches

No response

Response 1597

Perspectives on the postdoc roles and responsibilities

Personally, I feel that initial two years of postdoc positions is a learning platform for advancing career. Further, to execute our own ideas using that acquired skillset that might bring some novel and innovative concept.

Fundamental issues and challenges

Recruitment is one time event; however, too much less salary is the biggest hurdle in maintaining quality of life. Usually, postdocs are on that age when they are married and live with their children. They get

Existing NIH policies, programs, or resources

First to increase salary to respected amount. Make the policies that fix in hand salary for postdocs and fix the taxes and insurance in other head of the fund. So, that institutions do not interfere in salary head. Secondly, make biometric system to track the overwork and fix the pay/hour for that.

Proven or promising external resources or approaches

No response

Response 1598

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

No response

Existing NIH policies, programs, or resources

The current NIH policy that prevents postdocs from being considered employees of their institution for purposes of taxation and benefits is outdated and leads to undue burden that could easily be alleviated by changing this policy. Beyond the curbersome issues created by the need for the NRSA fellows to calculate and pay their own taxes, there are real negative consequences as a result of this policy. My health insurance is billed indirectly through a third party and I have had my insurance mis-billed and even cancelled multiple times during my NRSA fellowship. This has created undue burden and stress on my own family. I feel strongly that if the NIH does indeed value its postdoctoral trainees and the training ecosystem, this NIH policy needs to be revisited.

Proven or promising external resources or approaches

No response

Response 1599

Perspectives on the postdoc roles and responsibilities

Postdoctoral training is a step towards independence in academia. Practice in formulating your own questions and acquiring funding.

Fundamental issues and challenges

Wages.

Postdoctoral salaries are way too low.

Existing NIH policies, programs, or resources

Pay postdocs more.

Proven or promising external resources or approaches

No response

Response 1600

Perspectives on the postdoc roles and responsibilities

I view the academic postdoc as a position that allows for additional/orthogonal training to what was received during doctoral training. It is also a position one would take if they want to pursue a career in academia.

Fundamental issues and challenges

The primary concern is money. Taking a position in industry after finishing graduate school generally pays better. Also, working for a PI seems to have little to no protection compared to working in industry. Some

PIs are abusive, and there is little to no recourse for the abuse. Leaving a postdoc position without multiple publications effectively kills a career.

Existing NIH policies, programs, or resources

I recognize that there are significant policies, programs, and resources available. At the end of the day, working in science is exhausting. The primary thing that makes a difference is bringing home more money to have better stability for my family and having protections against abusive PIs. I am hesitant to take a postdoc position because I landed on a wonderful PI for my doctoral program and have witnessed the stark difference between him and nearly every other PI at my institution. I fear going anywhere else because I doubt many PIs would be as understanding of the fact that I have a family.

Proven or promising external resources or approaches

I cannot think of any.

Response 1601

Perspectives on the postdoc roles and responsibilities

I view the postdoc position as something to pursue only if you wish to have your own lab.

Fundamental issues and challenges

The poor pay. The lack of support such as healthcare, childcare, vacation time, affordable housing. Someone with a PhD shouldn't be asked to work for 50k.

Existing NIH policies, programs, or resources

Proven or promising external resources or approaches

Pay postdocs more money.

Response 1602

Perspectives on the postdoc roles and responsibilities

Considered as a training scientist with additional responsibilities like training junior staff, students (undergrad/graduates). Seen as having independence to steer projects and developing skills to lead an independent lab. Occasionally involved in lab management duties. Coordinating with other collaborators and staff with projects that are important to the lab.

Fundamental issues and challenges

Issues with compensation and benefits. For a professional, graduate degree, the compensation is far too low—not allowing for any leeway for family planning. This is driving talent away from academia and towards industry. The competition for NIH funding is way too stiff for a job that offers little in return. While anecdotal, there are still far too many instances where science undergraduates are being paid way higher as a starting salary and beyond, than a postdoc—how can anyone expect post docs to be satisfied with this way of life after spending at least 4 years in graduate school. Many PIs do not understand the struggle and use the NIH guidelines for salary, which is far too low and outdated in this day and age—this further demoralizes the postdoc academic workforce.

Existing NIH policies, programs, or resources

Increase compensation. BENEFITS: PROVIDE, PUBLICIZE and MAKE ACCESSIBLE. From healthcare, family planning, further education, children's education—give postdocs a reason to be happy with their life outside work.

Proven or promising external resources or approaches

No response

Response 1603

Perspectives on the postdoc roles and responsibilities

My students go into a postdoc for three reasons: they want to pursue academia, they are international students who need sponsorship and feel it's easier to get one as a postdoc than in industry, or they don't know what career path they want to pursue and thus use a postdoc as a "placeholder" while they figure this out.

I see a postdoc as a required step for a student who is determined to go into academia and is aware of the requirements/expectations of this career path.

Fundamental issues and challenges

Students often feel the career options for their degree are academia, where they are paid little, work intense hours, have few benefits, lack work-life balance, and don't see a clear/guaranteed career trajectory—or, industry, where they almost always start over six figures, work fewer hours, have stronger benefits, see work-life balance, and can better understand how promotions work/see a clearer career trajectory. In this comparison, industry almost always wins.

Further, postdoc hiring is almost a shadow process—it happens behind the scenes with PIs emailing other PIs, with no real job description or transparency, and the hiring process is highly inconsistent. In industry, networking is important but not everything; candidates find jobs online and go through a more transparent and standardized hiring process, and I think this feels safer and like they're more in control.

PIs also have too much influence in this process—students who want to pursue academia often change their minds after working with a PI who appears miserable or difficult, or who lacks appropriate mentorship/interpersonal skills. Often, students come into our institution intending to pursue academia post-graduation, but change their minds after seeing what the work environment of a lab is like, or seeing the negative long-term impacts of a high-pressure environment on other postdocs and the PI in the lab.

Existing NIH policies, programs, or resources

NIH sets guidelines for salaries, and this influences university salaries. Postdocs deserve more money, but universities won't change anything until the NIH itself changes.

Many PIs live and die by the science, and refuse to attend to things like mentoring their trainees or building their interpersonal skills. We offer optional mentorship trainings as well as multicultural trainings but the PIs who need these most fail to attend, and our school is hesitant to mandate this type of training for fear of upsetting the PIs as we rely on them for research, funding, and so on. The NIH should mandate mentorship trainings for PIs, if not also multicultural trainings. PIs have an incredible influence on the career trajectories of their trainees, and we're failing these students by not making sure PIs can appropriately mentor as well as reduce their personal biases in the lab environment.

The NIH should also have a policy about treating postdocs like other employees at the institution in terms of benefits (same healthcare plans available, same vacation days and sick time, etc.) and representation through human resources. Too often postdocs are treated like some sort of sub-employee.

Proven or promising external resources or approaches

No response

Response 1604

Perspectives on the postdoc roles and responsibilities

I view it as an opportunity to get the additional training/experience necessary to transition from grad student to PI, and a chance to develop more research with a new advisor before applying to faculty positions.

Fundamental issues and challenges

Postdocs are paid poorly relative to their life/career stage & expertise, and funding is difficult to come by. Also, as with all junior academic positions, you're very dependent on your advisor.

Existing NIH policies, programs, or resources

I think the paypack policy for the F32 grants is really awful and harmful; it has the potential to keep postdocs trapped in unhealthy positions, exacerbates the power dynamic between them and their advisor (because they can't just quit their job if needed), and keeps out people for whom paying back their salary would be such a disastrous option that they can't risk it at any cost. (I almost turned down my F32 offer because of the policy.)

Proven or promising external resources or approaches

Pay us more and remove the payback policy.

Response 1605

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

Salaries needs to be revised and adjusted to reflect the reality of cost of living. It really boils down to money for a highly trained work force that trying to start a family or settle down with an income that in some locations is barely above a living wage.

Existing NIH policies, programs, or resources

Given the efforts to help improve diversity in STEM fields, it would be beneficial that—just like it is done for responsible conduct of research—to require trainees to participate in culturally-aware mentoring training. This would not only help them identify improved ways of receiving mentorship themselves, but for those who go on to become independent investigators ensure they properly equipped with how to train the future diverse generation of scientists.

Proven or promising external resources or approaches

No response

Response 1606

Perspectives on the postdoc roles and responsibilities

A short-term professional position to develop the final skills necessary to independently develop and maintain their own research. An intermediary before beginning a professorship career.

Fundamental issues and challenges

Low pay for the education and skill set of a post-doc especially when compared to industry positions and increasingly extended times in a post-doc position before moving into a new job.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1607

Perspectives on the postdoc roles and responsibilities

A short term positions (2-4 years) to receive extra training and gain experience in a research laboratory before transitioning to a long term career in science and/or education.

Fundamental issues and challenges

A postdoc position in some ways feels like going back to graduate school with a little bit better pay. Unless someone is passionate about continuing in research and thinks a postdoc position will benefit their career development in a big way, it's more attractive to most PhD graduates to look into more lucrative industry

positions. For example, my partner who has a masters in biology makes nearly twice as much as me working for a bay area biotech company. I feel like there could definitely be more support for people who are interested in starting a family and being a postdoc. Especially for women, it feels like you have to choose one or the other. It'd be great if there was significant funds to support postdocs with children.

Existing NIH policies, programs, or resources

I think there could be better advertising of programs maybe. I'm part of the NIH-IRACDA program and I really like how there's an education training aspect of it, so more programs that support specific career goals would be good.

Proven or promising external resources or approaches

I appreciate being asked my opinion. Surveys like this and anonymous surveys give postdocs a way to express their concerns without fear of losing funding or facing other forms of retaliation. I think sending promotional emails and materials (emails, posters, etc.) to universities to disseminate to graduate students is a good way help make students aware of NIH programs.

Response 1608

Perspectives on the postdoc roles and responsibilities

As an academic postdoc, I am expected to leverage skills gained during my doctoral studies to independently work on and advance ongoing projects in the lab, assist and mentor more junior scientists, contribute to manuscripts and present at conferences. During my postdoc, I am also supposed to expand my professional network and grow soft skills that will aid me in pursuit of future positions.

Fundamental issues and challenges

Current academic postdoc salaries fail to compete with the rising cost of living and make it hard for postdocs to support themselves and their families. Additionally, they are significantly lower than salaries for comparable positions in industry.

Work-life balance is another source of contention that often attracts people to industry over academia, as academic positions are traditionally known for the lack of said balance.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1609

Perspectives on the postdoc roles and responsibilities

I see a post-doc as a way to shore up the skills gained during a Ph.D. I know why a post-doc is valuable for an academic career, but I wanted to enter into industry and still did a post-doc to shore up skills I felt were weak during my Ph.D. Post-doctoral training is valuable.

Fundamental issues and challenges

Recruitment—not an issue

Retention—I think individuals who want to enter into industry tend to leave more quickly while intended gov't and academic career post-docs stay longer.

Quality of life—HUGE ISSUE—THIS SHOULD NOT BE ALLOWED TO BE A SECOND PHD, OTHERWISE, THERE NEEDS TO BE A RE-EVALUATION OF THE PHD TRAINING PARADIGM. And training should actually happen. So many PIs don't take the training portion of this seriously and just appreciate a set of hands and let department activities train their people. I don't know how NIH necessarily helps with this as the average post-doctoral appointment creeps up in length.

Existing NIH policies, programs, or resources

I think the NIH already does a lot. Your websites are a bit tortuous and could contain more summary information and navigation aids. I would like very clear summaries laid out for students on training grants as to how many years they can be supported on one as a Ph.D. or post-doctoral researcher. Also, very obvious specific statements at the tops of grant web pages as to how many grant cycles at the start of a Ph.D. or post-doc can a trainee apply for would be great. Maybe even an interactive checklist with an immediate answer output.

Proven or promising external resources or approaches

PIs taking on undergraduates, graduates, and post-docs could be made to undergo annual training on managerial skills, team leadership, and conflict resolution. It would be great if it were mandatory for PIs to invite review by their trainees on their leadership. Also, PIs should essentially be training their trainees to take their position or enter into leadership positions when they move on. It would be great if PIs had to introduce you to the facets of their jobs 2-3 times per year and if PIs had to tell you a week in advance when they would be no-contact for an extended period of time. (I learn in meetings with other professionals when my PI is leaving. He often doesn't tell anyone and leaves for days at a time, but he becomes upset if you work unsupervised while he is away.) It would also be phenomenal if PIs had to allow opportunities for internships when requested. I know several people who were guilted out of accepting or applying for experiences that would have benefitted their careers because their PI told them it was inappropriate or directly told them they couldn't because the PI didn't know how to run various things in their own lab to allow the trainee to leave.

Response 1610

Perspectives on the postdoc roles and responsibilities

Scientifically this is an excellent possibility to get training beyond the PhD, learn a new field and expand network.

Fundamental issues and challenges

Pay the minimum salary!! We are working under very bad circumstances and then [redacted for anonymity] even doesn't pay us the agreed minimum postdoc salary. While this is clearly not official policy, some [redacted for anonymity] departments (not all) give postdocs a different title to avoid the minimum salary requirement. This is ridiculous, and should not happen!

Existing NIH policies, programs, or resources

See above.

Proven or promising external resources or approaches

No response

Response 1611

Perspectives on the postdoc roles and responsibilities

To continue developing scientifically, gain new technical skills or scientific perspectives; to gain experience in mentoring, teaching, and grant writing; to establish some independence as a scientist; to explore careers and apply for jobs.

I believe the postdoc experience should serve as a bridge between PhD training and an established career but is only necessary for people who need this bridge and should be short. It should be clearly focused from the beginning on the goals (eg, filling gaps in CV, learning a new discipline) and the advisor should be aid the postdoc in the transition rather than incentivized to retain the postdoc for cheap labor for extended periods of time. Academic postdocs are mainly beneficial for tenure-track scientists but it seems so mainly for CV boosting/politics rather than actual developmental necessity.

Fundamental issues and challenges

The compensation and benefits are extremely poor and the learning/growth are not as substantial as one would experience in a permanent role. It takes time to generate publishable science, especially when

entering a new field or advisor/industry. Ultimately it feels like a postdoc is an expedited PHD2, where you have the basics of independent science mastered, but you are no longer the expert in your area (as you were at the end of PHD1). At this point in people's lives, they may have student loans, want to have children, buy a house, establish themselves in a location; the postdoc does not offer support for those things. The salary is barely enough to live. The benefits are much worse than industry or professor positions, and it is a temporary position that may require moving to begin and moving after its complete. There are significant limitations for postdocs on T32 grants hoping to gain a tenure-track faculty position as they prohibit supplementing stipend and some research funds with other government-funded grants. so there is little incentive to apply for NHS funding which later prohibits them from being competitive for tenure-track positions since they lack a funding track record. There is often larger expectation of postdocs to have non-science roles (ie, teach, mentor, write grants) and therefore, it is more difficult to be scientifically productive (the main metric of evaluation).

There is little support from NIH or institutions on how to navigate the transition from postdoc to tenure-track faculty.

Existing NIH policies, programs, or resources

Higher salary caps, longer paid parental leave, more $$ and support for conference travel, more flexibility of T32 grants to supplement salary/stipends with other grants. A better mechanism for postdoc to K to R pathway. Currently a postdoc wanting to apply for a K needs to have insitutional support. If the postdoc wants to change institutions, this is incredibly challenging to orchestrate under the current funding pathway.

Proven or promising external resources or approaches

No response

Response 1612

Perspectives on the postdoc roles and responsibilities

I think the value of the postdoc position is becomingly increasingly unclear for those who do not want to pursue tenure track positions. While marketed as a "training" position, it seems like you just continue working long hours similar to graduate school and are not compensated to the level that your experience would require in a non-academic environment. The lack of clarity around the length of a postdoc, what the deliverables are, and what exactly your role within both a given lab as well as the larger institutions creates an environment filled with anxiety and, at times, toxicity.

Fundamental issues and challenges

The compensation (salary, benefits, 401K) must be improved to recruit and retain postdocs. If I can make 1.5-2x as much in industry and contribute to my retirement fund all while doing exciting science, why would I pursue a postdoc position? Why would someone stay in a postdoc position if they receive an offer in industry? This leads to a decrease in the workforce that is required to perform the research outlined in most, if not all, grants and slows down research. I also think the lack of the compensation can exclude individuals from lower-socioeconomic and first-generation backgrounds from pursuing these positions. Identifying as both, it is hard to justify financial and quality of life costs of pursuing a postdoc, even though the research is exciting.

Existing NIH policies, programs, or resources

Increase the allowable budgets for salaries and increase the minimum salary level, with a scaling factor for cost of living. Also provide more structure for mentors and institutions for the duration and deliverables of a postdoc position. While obviously these will vary by field and project, having at least some guidance is better than nothing.

Requiring IDPs or similar plans, and regular check-ins/updates/progress reports, for all trainees whose research and/or stipends are directly supported by federal grants. At the moment, it seems like something you fill out but do not have to actively maintain unless the individually is motivated to do so and can be difficult to use when a mentor is not supportive or apathetic towards the process.

Proven or promising external resources or approaches

No response

Response 1613

Perspectives on the postdoc roles and responsibilities

The academic postdoc model is outdated and I am glad to hear that graduate students are finally seeing it for the exploitative dead-end proposition that it is. I have been a faculty member for five years after nearly a decade as a postdoc. From the postdocs' perspective, the position is a way to continue performing research temporarily while waiting for a suitable (or unsuitable) faculty job to materialize. It's fun at first; postdocs mostly just do the research they love without the pressures of a graduate student or the responsibilities of a faculty member. Over time it becomes more stressful to continue working for low pay in a temporary soft money position with the knowledge that the majority of postdocs do not get faculty jobs. Meanwhile, PI's find it difficult to get grant funding without large-scale, labor-intensive projects, so the PI with the most postdocs wins. In many STEM fields faculty are still recruited out of graduate school, without further training. If NIH considered postdocs to be trainees, the priority would be on keeping them in the workforce after investing in their training. It sounds as though NIH is concerned about PIs being unable to find fresh young postdocs when the old ones expire (pass the K99/ESI cutoffs and give up on a science career), however, which is unlikely to be a useful attitude in solving this problem. Personally, I am not hiring postdocs and I am honest with my graduate students about their prospects should they choose that route.

Fundamental issues and challenges

Aside from being underpaid and having uncertain job prospects, postdocs are also vulnerable in other ways. They depend on soft money, and if a fellowship or PI's grant runs out they are forced to find a new position and may need to abandon projects. They have little recourse in case of a conflict with a PI except to seek a new position, which similarly may result in lost work. As far as recruitment, consider that people are being recruited to spend a few years competing with each other for scarce jobs, and there is no consolation prize for the ones who fail. It's a tough sell, even if you ignore the poverty.

Existing NIH policies, programs, or resources

NIH needs to decide how it wants to structure academic research. If research is conducted in teams consisting of a PI with multiple trainees, there are only two options—either permanent jobs are created at an exponential rate to absorb trainees, or the trainees are culled. Decades ago when universities were expanding and labs were small a short postdoctoral fellowship akin to a residency made some sense. Predictably, making cheap, highly-skilled labor available led to larger labs and the inevitable slowdown in faculty hiring left postdocs trapped. NIH policy is to cull postdocs by setting time limits on F32/K99/ESI programs, so that postdocs must either quickly secure a faculty job or leave science. If the goal is to continue with this system of churn, it will be difficult to keep enticing more grad students. There must be jobs waiting for them. If NIH wants PIs to keep working with teams of temporary trainees, there need to be fewer trainees to lower the competition for jobs. If NIH wants PIs to keep working with large teams, there need to be permanent well-paid positions on those teams that are not contingent on grant renewals.

Proven or promising external resources or approaches

NIH will need to work with universities to reform the research system. Either stop allowing universities to use NIH funding to expand the number of grad students and postdocs beyond what the job market can absorb, or redirect funding to establish permanent non-faculty positions for full-time researchers. The latter option is probably the best investment NIH can make, in terms of retaining the valuable, highly-skilled scientists whose training is wasted in the current system.

Response 1614

Perspectives on the postdoc roles and responsibilities

I view it as an opportunity for professional development and career mentorship to make me a more competitive candidate for career progression.

Fundamental issues and challenges

PI's either micro-manage postdocs as if they are high school students or do not provide sufficient guidance and mentorship.

PI's and study coordinators seem to expect postdocs to be available after hours and weekends and manage duties/ studies outside the scope of work hired for. Any difficulty reflects poorly on the Postdoc. This is not good for Postdoc quality of life and retention.

Existing NIH policies, programs, or resources

Introductory workshops on scientific research writing, how to use Rstudio and other data analytic tools, communication skills for managing up and managing down, offer hybrid remote and in-person work days, subsidize parking passes for on-campus parking.

Proven or promising external resources or approaches

Mentor and mentee training workshops, Postdoc association social activities, allowing postdocs to participate in writing, teaching, mentorship, and data workshops, medical librarian led workshops.

Response 1615

Perspectives on the postdoc roles and responsibilities

It's an opportunity to gain experience in an area that you did not get exposure to as a graduate student that you will need in your future desired career and to develop more independence as a researcher in order to start your own lab (if desired)

Fundamental issues and challenges

First, I actually think it's not an issue at all if postdoc recruitment/retention has decreased—in fact I think it's necessary given that a small fraction end up being able to start their own labs in academia. Doing a postdoc has a huge opportunity cost and most postdocs end up not reaping the benefits of securing a faculty position. Why would you want more people to take this gamble? It's exploitative. Second, I wonder how postdoc retention is being measured here—is publication required before leaving? If the purpose of a postdoc is to gain desired skills for biotech research positions, then a postdoc is complete when they've gained experience in that area (which happens prior to publication).

However, if the goal is to retain postdocs until they publish, then they need to be offered benefits that rival what they can get in alternative careers. This means 100k minimum salary, 401k matching, parental leave, vacation days. I think reducing the number of postdoc positions to increase the salary/benefits for those who choose to do a postdoc could work. I'm sure faculty would not be happy with this suggestion but with the explosion of biotech opportunities and decrease in open faculty positions, this problem will only get worse over time. As a former postdoc in the bay area, I have seen peers with families to support on a 60k stipend where the median rent for a 100 yr old 2 bedroom apartment is over $3500, lining up on weekends to pick up free food boxes. These are the top PhD graduates in the country who could get jobs paying $150k+ and with good work life balance just down the street. The slight chance that they could become a professor somewhere just often isn't enough to convince them to stay.

Existing NIH policies, programs, or resources

Greatly increasing the NIH minimum salary, maybe with a multiplier based on cost of living.

Greatly reduce the number of open postdoc positions to make the salary increase possible (perhaps have a max number of postdocs allowed per grant). This will also help to increase percentage of postdocs that becomes faculty.

Require universities to provide subsidized housing at a max rate for all postdocs.

Require universities to provide parental leave and additional subsidies for postdocs with children.

Provide retirement benefits.

Proven or promising external resources or approaches

Apart from financial opportunity costs of a postdoc, one major driver of postdocs leaving is a difficult advisor. This is far too common and anything that can be done to make advisors accountable would be

helpful here. Perhaps requiring anonymous letters/ratings from trainees, both current and former, when applying for NIH funding. This has been done for tenure/promotion at the places I trained but should really be done more often.

Response 1616

Perspectives on the postdoc roles and responsibilities

To me this role is an extension of graduate work with more independence and responsibility, but less training and support. High pressure job with low salary not commensurate with experience, and potentially negative impact on job prospects due to lack of professional skill building for most careers.

Fundamental issues and challenges

Beyond the issues of low salary and lack of professional development support, I decided not to do a postdoc for two main reasons. The impression that it would be an isolating experience and that the work would not be impactful. I am interested in social justice and integrating participatory research, quality pedagogy, mentoring, and community building into my career. In my field (molecular biology/immunology/neuroscience) I didn't see many opportunities for postdoc roles where I could do these things and be supported and rewarded for them.

Existing NIH policies, programs, or resources

Having opportunities and training in community engagement and participatory research for basic science. Not just "outreach" and education programs but collaboratively building research priorities and programs with affected communities. Having funding mechanisms and staff support for diversity, equity and belonging initiatives, and for improving teaching practices, and postdoc roles that explicitly include these activities in the job description.

Proven or promising external resources or approaches

See above. Also better relationships with industry, government, non profits to set up internships/fellowships/collaborations for postdocs. This would help set them up for success after the postdoc.

Response 1617

Perspectives on the postdoc roles and responsibilities

1. A continuation of graduate training, which means there should still be learning and mentoring resources covering both technical skills and professional skills (writing grant, etc)
2. A platform for more independent research. This means the mentor should be open and supportive of postdocs' own research ideas

Fundamental issues and challenges

1. Low income
2. Lack of mental support from advisor. Being more independent doesn't mean being left alone in a dessert

Existing NIH policies, programs, or resources

1. Higher salary for postdocs
2. Provide an anonymous platform for trainees to review PIs so that people can avoid toxic PIs

Proven or promising external resources or approaches

No response

Response 1618

Perspectives on the postdoc roles and responsibilities

The role of the postdoc is to develop and conduct near-independent research projects/programs, with the supervision and guidance of a supervisor. They have a high degree of technical expertise, but are not simply skilled technicians who conduct research planned by someone else, and play a fundamental role in the conceptual development of projects.

Fundamental issues and challenges

The most fundamental challenge to recruitment, retention and quality of life of postdocs is pay. This is particularly true for postdocs in cities with high cost of living, where the best research institutions also tend to be located. This is compounded by the expectations of postdocs to work extremely long hours, suffer through repeated failures, and with a low chance of securing a long-term position (see below). I believe it is unreasonable to expect sustained recruitment and retention of postdocs when they are expected to work 80+ hour weeks while also expecting them to spend over half their income simply on rent, yet alone other basic costs of living. This creates a very poor quality of life and can also negatively impact research quality/production. This is particularly prohibitive to people from lower income families and disadvantaged backgrounds, as well as postdocs who have started or wish to start their own family. Obtaining a PhD and pursuing a postdoc should not only be for people who's "Papa Has Dough (PHD)" as one PI once told me. And as mentioned above, the low pay is exacerbated by the high work demands on postdocs and the often hostile work environments they work in. PIs are incentivized to push postdocs to work harder and longer to generate publications and grants, while having little incentive in reality to promote the professional development of postdocs. Tenured PIs are also highly protected from negative consequences from how they treat their employees, while postdocs have vulnerable employment (contracts are only one year long) without common protections (e.g., severance pay). This creates an environment ripe for PIs to take advantage of postdocs. This is potential is even greater for international postdocs whose visas are tied to their position.

Existing NIH policies, programs, or resources

The NIH directly regulates postdoc pay in the US through their minimum stipend levels. Even if individual PIs wish to pay their postdocs more, this can be challenging to justify in budgets for grants if the NIH and institution minimum is lower. The NIH should modify it's minimum stipend levels to help ensure postdocs have a living wage across the US. Some may be hesitant to simply increase the minimum stipend levels across the US as it may not be feasible or unfair across different research institutions. After all $56,000 goes a whole lot further in Pittsburgh compared to New York City. However, I believe a minimum stipend that is scaled by the cost of living of where institutions are located should be considered.

Proven or promising external resources or approaches

NIH should develop programs to improve the mentorship and partnership of PIs with their postdocs. NIH should provide mandates for institutions to provide formal mentoring training as well as monitor mentorship performance and employee treatment of NIH-funded PIs. This should help improve mentorship skills and also help give incentive for PIs to provide a beneficial working environment for PIs.

Response 1619

Perspectives on the postdoc roles and responsibilities

Even though it is the path to be a professor it is not accesible to everyone due to the financial burden of those that decide to pursue a postdoc. For example, delayed 401k contribution, issues on getting a house due to lack of real income and delayed family planning due to lack of resources for postdoc with families

Fundamental issues and challenges

Income is too low for someone that already has the highest degree possible. You have to decide between starting a family getting a home or continue nourishing your scientific career.

Existing NIH policies, programs, or resources

Parental benefits, real income, 401k retirement assistance.

Proven or promising external resources or approaches

No response

Response 1620

Perspectives on the postdoc roles and responsibilities

A postdoctoral position amounts to the fleecing of the next generation of scientists. Most of my former postdoc colleagues, including myself, felt like they were being devalued and dehumanized on a daily basis by the system and the PI. In most labs, the postdoc is responsible for training graduate and undergraduate students but have never actually received any formal training themselves on how to lead teams or provide constructive feedback. Postdocs are in a state of purgatory because it is abundantly clear there are very few paths to a professorship but are not allowed to receive career training from their institutions on how to transfer their skills to non-academic careers.

Fundamental issues and challenges

SALARY and LACK OF RESPECT! The quality of life for a postdoc is not much better than a graduate students because they are still struggling to cover basic necessities. There is almost a huge time drain insisted upon them by the PI to train others and keep the lab running in their absence. This causes an overwhelming amount of stress and burnout. In fact, there are lots of postdocs who will say that the stress and financial insecurity has caused them to put their family plans on hold thereby depriving them of one source of happiness. The lack of diversity in the academic ranks also is major red flag for postdocs from historically marginalized communities. Toxic work environments and lack of leadership training for academic advisors are leading causes for postdocs to jettison to industry roles. A solution would be to compensate postdoc with salaries on par with their industrial counterparts as money can and will provide security and happiness to those that have never experienced it prior to obtaining a Ph.D. It would be worthwhile to have a scoring system for grant applications that is tied to the PI’s lab or institution ranking of diversity and retention. This scoring could be obtained by requiring feedback from all of the lab’s current graduate students and postdocs to understand if funding the grant will actually help further their careers in addition to the PI’s. I’m sure if the NIH was to ensure that the feedback would not be disclosed to the PI then graduate students and postdocs would be more inclined to provide honest feedback.

Existing NIH policies, programs, or resources

You could mandate a higher salary and access to university sponsored career training and resources for postdocs for any NIH funded grants or institutions.

Proven or promising external resources or approaches

No response

Response 1621

Perspectives on the postdoc roles and responsibilities

Learning new skills or training for academia-track position.

Fundamental issues and challenges

It is exploitation. Post docs are doctors who do 4x the work for 1/4 the income. Poor pay, poor quality of life.

Existing NIH policies, programs, or resources

Proven or promising external resources or approaches

More pay. Less exploitation.

Response 1622

Perspectives on the postdoc roles and responsibilities

The academic postdoc is a unique period of time where the trainee learns a new expertise in a new environment. Simultaneously, the academic postdoc can utilize their existing skillset to grow the host lab's scientific research in new directions, which may give a foundation for their own science in their independent career. In my perspective this is often where and when the most innovative science can emerge.

Fundamental issues and challenges

Fundamental issues include

1. competing postdoctoral positions in industry tend to be higher paid and
2. immigration barriers for international postdoctoral trainees to come to and hopefully stay in the USA.

Existing NIH policies, programs, or resources

Postdoctoral fellowships that support international trainees will ensure that we attract the best talent to come to the USA. Existing programs and resources can be expanded to ensure that the postdoctoral salary is competitive and the training enterprise remains strong. There is also often travel support for graduate students and not for postdoctoral fellows that hinders the overall ability of postdoctoral fellows to network in the scientific community and augment their CVs.

Proven or promising external resources or approaches

No response

Response 1623

Perspectives on the postdoc roles and responsibilities

An academic postdoc has a diversity of roles and responsibilities. Their contribution in advancing the research enterprise is obvious. They are highly trained and largely responsible for advances in academic researcher laboratories. The postdoctoral experience provides career opportunities and growth for the scientists to choose a career path of interest. To achieve both of these goals, the mentor and mentee need to be on the same page to manage expectations.

Fundamental issues and challenges

There are many fundamental issues. I believe the largest issue is career opportunities after postdoctoral training are somewhat limited. In some ways, graduate students are surveying the opportunities and deciding that postdoctoral training is often not necessary to pursue their career goals. We cannot flood the market with postdoctoral trainees if there's nowhere for them to go after training. Another issue of course is recruitment of talented postdoctoral opportunities when salary compensation (and benefits) is considered low relative to other opportunities. This is a double-sided issue of course, as if you increase postdoctoral salaries we could have a flood of postdocs increasing the talent pool with further diminished opportunities post training.

Existing NIH policies, programs, or resources

Over the years academic institutions have pushed the burden of supporting graduate students almost entirely on federal agencies, in this case NIH. I believe NIH needs to push back , particularly for graduate education to make institutions more responsible for those costs. There is an obvious need is to increase support for the training mission of NIH, and this training should not be delegated to individual PI grants, but instead to fellowships. A substantial expansion in NRSA individual awards could be helpful as opposed to postdoctoral slots on T32's. The NRSA application process intrinsically selects for postdocs with a genuine interest in pursuing research. Further, since they are awarded to the individual, it provides better opportunities for career engagement. These NRSA's have become very competitive and discouraging to applicants.

Additionally, the challenge with international scientist is enormous. There is tremendous global talent, and many of these postdocs are not eligible for some of the funding mechanisms. If we continue to have a loss of domestic postdoctoral candidates, we need to increase mechanisms for funding international postdocs.

Proven or promising external resources or approaches

I think this RFI is a good first step, as are the planned open forums to get different perspectives. I do not think the solution is to simple throw more salary and benefits to postdocs. These are training programs and I believe postdocs need to understand and use postdoc training time accordingly. Postdoc should not be careers. Long-term postdocs could become exploited. I do believe most of the challenges postdocs are currently encountering are not from their actual training, but rather the opportunities waiting for them after the commit there energy and time to their training. It more postdoctoral slots were linked to post-training careers, I believe much of this anxiety and dissatisfaction would be diminished.

Response 1624

Perspectives on the postdoc roles and responsibilities

Transitional period between terminal degree and independent research position, designed to provide training opportunities under conditions with adequate support from senior scientists.

Fundamental issues and challenges

Many people are choosing not to do postdoc simply because they have no desire for a career in academia, which I think is a separate issue in of itself. Most people see the hardships and life style of principle investigators, especially young investigators, and decide it is too difficult of a career track. In some cases, these individuals choose to find careers in industry because they are under the impression that a non-academic job will be more personally rewarding, and industry does not always value postdoc experience because it is seen as a way of grooming people for academia.

Overall, a stigma has developed where a postdoc is viewed as an inconvenient step on a ladder toward an academic career, and not a personally rewarding training opportunity that could provide a wide range of training geared toward many different career options.

Existing NIH policies, programs, or resources

When most extramural researchers think of NIH they think of funding opportunities. Learning to write grants is still one of the greatest barriers to an academic career. Most postdocs who receive salaries from research grants like R01 or R35 don’t feel the need to start writing grants because their PI will basically do it for them. Many people are deterred even from trying to write F or K series proposals because they find it too difficult. Even though these are very rewarding experiences in grant writing and can provide significant support, the amount of time and effort it takes to write these coupled with the length of the grant review process can be intimidating (it can take over a year to write, submit and review a proposal while a postdoc position might last only 1 or 2 years for some people).

I think if there were F and K style grants which awarded smaller amounts of money for partial salary and research support, had a more rapid/frequent review cycle (more than 3 submission deadlines per year with expedited review time) and awarded a relatively high number of applicants then young scientists would feel less intimidated and pursue these opportunities. In turn they would learn early on how rewarding the grant writing experience can be, which would encourage an academic career.

Proven or promising external resources or approaches

Maybe NIH staff attending scientific conferences could host workshops directed at postdocs specifically, giving them a chance to promote awareness of NIH resources while also providing a direct interaction with postdocs. This would be the best way to really observe individual’s opinions and experiences.

Response 1625

Perspectives on the postdoc roles and responsibilities

Postdocs are a lifeline for innovation and faculty development. They are the scientific workhorses in many labs, receiving hands-on training, generating first-author papers, and developing the skills and experience needed to transition to early career investigators.

Fundamental issues and challenges

As a T32 director I am frustrated that some of the brightest trainees emerging from our clinical training programs are not eligible for T32 (or most K-level) support because they are not citizens or green card

holders. This is a systems-level obstacle to the diversification of our workforce, and driving trainees from diverse backgrounds into clinical roles rather than investigators. These individuals often have substantial debt from their graduate or medical training. That our primary funding pathway for postdoc and early career development does not provide non-citizens support is translating into lost opportunities for all of us.

Existing NIH policies, programs, or resources

End the citizenship requirement for T32 and K-level funding. If the concern is that foreign nationals will take the training and then go back to their home country, then there need to be incentives in place to encourage US citizenship as part of postdoctoral and early career training.

Proven or promising external resources or approaches

As above.

Response 1626

Perspectives on the postdoc roles and responsibilities

My idea of a post doc is someone who is looking to go into academia and wants to have more experience/publish more papers. They seem to have equal responsibilities as graduate students and work relatively similar hours (not 9-5, on weekends, etc).

Fundamental issues and challenges

The pay is awful. Candidates just spent 4+ years barely making minimum wage and now that they have a doctorate they still are barely scraping by in most cities. Additionally, most post docs are in their prime family-building and wealth building ages. It is nearly impossible to support a family and also save for retirement, and the lack of an employee-sponsored 401k (or similar) + match is debilitating to retirement prospects. Additionally, many institutions do not even provide benefits like child care and have minimal/bad healthcare that typically does not include vision or dental. Jobs outside of academia, even if they pay the same salary, almost always offer these retirement, health, and wellbeing benefits that are a large draw for people that are typically in their 30s.

Existing NIH policies, programs, or resources

Raise the R01 amount—PIs often want to pay/compensate their post docs and grad students but have no more funds. also it is important to consider that prices of reagents and equipment have also gone up in the years since the R01 amount has changed.

Proven or promising external resources or approaches

No response

Response 1627

Perspectives on the postdoc roles and responsibilities

Postdoctoral fellows are not trainees. They have completed their training, which is what the PhD represents. They are professionals, who have the developed the skills required to execute intricate, complex and deeply technical work to produce biomedical research that supports USA healthcare. They should be treated as such.

Fundamental issues and challenges

For the past 30 years inflation and wage stagnation have eroded the standard of living of those who work in academia to near poverty. This means that many postdoctoral fellows are unable to support a family or be financially responsible while earning only their full wages. Many must work second jobs to supplement their income which has the deleterious effect of distracting from their main career.

Existing NIH policies, programs, or resources

NIH salaries guidelines are an embarrassment to science. Postdocs have by definition earned an advanced degree, yet the dismal wages standards set by the NIH would leave them near poverty, barely able to afford basic housing and living standards, let alone consider the ability to begin or support families.

consider that many other professions offer far higher compensation with a mere college diploma. This dissuades any college graduates with any sense from pursuing academia, and relies heavily on the import of postdoctoral candidates from abroad.

Proven or promising external resources or approaches

If you want to attract better people, offer better wages. You could likely redirect all funding dedicated to mentoring towards salaries and be far better off.

Response 1628

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

Job prospects in academics are poor for postdocs. As Chair of a basic science department, I can report that 300 applicants apply for a single, tenure-track position. This would be okay if there were alternative academic paths for postdoctoral trainees. There aren't. In my view, this is a terrible situation that represents a structural flaw in the funding system. With much funding in my area supported by R01s and R35s, there is very little incentive and in fact a disincentive to hiring a postdoc as a senior researcher in a lab. Pretty quickly, the salaries of such individuals can double if not triple that of a graduate student. Hence, there is a systemic force to pass over senior researchers in favor of graduate students, despite the fact that they can provide continuity, maturity, dependability, and wisdom to a lab, just to name a few of the traits. In my view the solution is simple. NIH needs a funding mechanism to support senior researchers—not even to pay their salary all of the time, but to reward them for achievements and idea and to agree to support them for a length of time, such as 5 years (not even with any expectation of renewing). This would i) support the research endeavor, ii) define a track that many postdocs would be happy to pursue, and iii) encourage PIs to hire and retain such individuals, especially the talented ones, with such a new financial calculus. Even if a postdoc does not pursue such a path, it renders being a postdoc more attractive, by defining another rewarding and realistic career path.

Existing NIH policies, programs, or resources

See answer above. Creating a funding mechanism for postdocs that have graduate to senior research (ideally in a lab outside of the postdoctoral training).

Proven or promising external resources or approaches

No response

Response 1629

Perspectives on the postdoc roles and responsibilities

Learning new topics do more research publish more practical papers and training

Fundamental issues and challenges

The rents are getting much higher that I can afford to live comfortably next year, the benefits and insurance and parking at my institute also are expensive. There's no clear path if my PI can apply for my green card and how she needs to proceed.

Existing NIH policies, programs, or resources

Breaking down some findings and allowing PI to use them for postdoc life quality. Having NIH policy to include that there shouldn't be a maximum salary for postdocs. My PI tried to increase my salary and the department didn't allow because of the maximum salary rule that exists in the department, however, if NIH put the word out that there shouldn't be a maximum she could've done it.

Proven or promising external resources or approaches

No response

Response 1630

Perspectives on the postdoc roles and responsibilities

With the ongoing over killing competition, there's no clear avenue for securing a job after the long training period. Therefore, people tend to leave academia to industry

Fundamental issues and challenges

No response

Existing NIH policies, programs, or resources

1) Increasing postdoc salary to commensurate with the level of education specially with the ongoing inflation.
2) Limiting training to 3 years max, and establishing a clear scientific pathways for what trainees could to do after concluding training

Proven or promising external resources or approaches

Increasing research funding

Response 1631

Perspectives on the postdoc roles and responsibilities

A postdoc position is supposed to be time in your career to receive additional training in new techniques and field of research. A postdoc should be receiving mentoring specifically to increase their professional development. They can also work on developing independent research projects that they can take with them to a new position.

Fundamental issues and challenges

Many postdoc advertisements that I see list several necessary technical skills that the applicant must already have to gain the position. This means the applicant would not be receiving training in new technical skills. Fundamentally, postdoc positions have lost a lot of the training and mentoring aspects and instead are just ways for labs to hire highly skilled but cheap labor. Many postdocs are treated as staff scientists in all ways except pay. Furthermore not all career paths require a postdoc, so there is no reason for many to pursue a postdoc.

Existing NIH policies, programs, or resources

Postdocs need to be paid significantly more if they want stay competitive.

Proven or promising external resources or approaches

More money for postdocs.

Response 1632

Perspectives on the postdoc roles and responsibilities

A post doc should be energetic and working for his mentor. A postdoc relationship should be a symbiotic mentor-mentee relationship. The goals should be to develop the career of the postdoc and contribute to the work of the lab. The postdoc should be able to leave the host lab with excellent published papers and with preliminary data and a path toward a k99, R21 or R01 application. The host lab should be left with some excellent papers that represent a body of work that form a basis for new thinking. The mentor should have an almost daily, informal interaction with the post doc.

Fundamental issues and challenges

1. Low salary
2. Weak postdoc association

Existing NIH policies, programs, or resources

1. K99 grant should be in two categories 1-4 year postdoc and 5-10 year postdoc (who never got promoted or not got any grant)
2. T32 grant should be 3-5 years which give the basis for the preparation of mk99

Proven or promising external resources or approaches

NIH needs to reform its policies regarding post-docs:

1. The salaries are too low and not competitive with those in Europe.
2. The prohibition on supporting non-US citizens is a self-inflicted injury on American science. It means we turn away many talented scholars from around the world. In fact, there should be more international outreach to countries that are under-represented in American science (e.g. every single African country). This would greatly enrich the cultural and racial diversity of American science.
3. The limit of 3 years of support on T32 and F32 grants is unnecessarily rigid.

Response 1633

Perspectives on the postdoc roles and responsibilities

I think postdocs should be first getting leadership and management skills for scientific research. Second to this is training in additional scientific skills.

Fundamental issues and challenges

Leadership does not seem to care and is out of touch. We just went through a pandemic where anyone with young children really, really suffered with school closings. Leadership everywhere did not, and still does not, seem to fathom what a toll this took. Nobody lifted a finger to help young families and they still don’t seem to get how challenging this was and how much everyone in this position is exhausted, falling behind, and stressed as a result of not being able to work at normal levels. A little concern through thoughtful emails and meetings to ask what they can do would go a long way. Make grants and postdoc funding more easily extendable, eliminate paperwork, and offer increased pay and child support. Really, postdocs just want someone to express a little sympathy and show some curiosity about how to help. Show some emotional intelligence or get appropriate training on emotional intelligence. This survey is a good baby step forward.

Existing NIH policies, programs, or resources

All postdocs should have to apply for funding and be asked to do more independent work. They should supervise 1-2 people. Right now, doing a postdoc is like basically doing a 2nd PhD and postdocs do not learn any management or leadership skills. This is a HUGE problem. We need to fundamentally rethink postdocs as a position that trains in leadership, as they would get in industry. In addition: get rid of K99 awards. They basically are given to postdocs who need more training (i.e. are apparently lacking in some way) but are also viewed as the top-tier award for excellence. This is an obvious contradiction. Give out awards based on promising proposed research and previous accomplishment (and give it early in the postdoc —and make it extendable for longer). Stop this awful K99 program that rewards people who failed to get enough training in the early part of their postdoc.

Proven or promising external resources or approaches

No response

Response 1634

Perspectives on the postdoc roles and responsibilities

Transitioning from a student to a postdoc should have the goal of learning new skills and thought. Postdocs should be encouraged, but not required, to seek external funding for salary or research expenditures. Postdocs should be treated as junior faculty and not a student considering they are more similar to junior faculty than students. In this regard, postdoc responsibilities are not dissimilar from a faculty member. They should be conducting rigorous experiments, reading new literature, writing for

publication or funding, reviewing papers for journals, be involved with the institution, department, and societies, and build collaborations.

Fundamental issues and challenges

Based on the similarities to junior faculty, postdocs should be paid similarly. Most experiments are conducted by students, postdocs, and research technicians and they are payed substantially less than the principal investigator (PI). Having been a postdoc at two institutions, many PIs have no sense of their lab culture, how experiments are conducted, or how results are obtained. Moreover, postdocs are systemically stuck to be viewed as inferior or unknowledgeable. For example, postdocs can not apply for R01 grants or many institutional grants due to their position title, or opinions and positions are not valued due to "inexperience/youth". Postdocs, especially international postdocs, can be exploited to work long hours or procure data unreasonably, or face being fired for "inadequate performance". In summary, postdocs are treated as inferior, payed inadequately for their skills, and often systemically stuck to be a postdoc for many years until they become junior faculty. Alternatively, industry pays twice as much as being a postdoc and allows the postdoc to begin life. Many postdocs are not given junior faculty status until extramural funding is procured like a K-award or career development award which typically doesn't occur until their early to mid 30s. Given that most institutions do not provide matching retirement for postdocs, this presents a systemic problem for attaining wealth. While many of my peers began working and saving for retirement in their early 20s, I will not make enough to save for retirement until my mid-to-late 30s. That's almost 20 years of compounding interest and inflation that postdocs can not capitalize on because of the path they chose. Lastly, many current postdocs feel tenure is going away which means our final position as a faculty member will never be secure.

Existing NIH policies, programs, or resources

Postdocs need to be treated as faculty members. In this regard, they should be payed more. Postdocs are often payed through NIH grants which stipulates they can only make as much as the NIH pay scale from NIH grants. Anything above that must come from other funding sources. This should be removed. Nearly all PIs pay postdocs according to this scale making "shopping around" pointless. If postdocs could be paid more through NIH funding that would allow PIs to pay more to reach competitive postdocs allowing postdocs to seek better opportunities much like other job industries.

Postdocs can not apply for many grant mechanisms as they are a "trainee". This should be removed to allow postdocs to seek more funding opportunities for research and salary.

Much like other government sectors, NIH should adjust funding to meet the expense of the area. Direct costs of 250k/year goes much further in rural areas compared to urban areas. For example, Seattle/Boston-area institutions must pay their research technicians much higher than Birmingham/Dallas-area institutions.

Indirect costs should be better accounted for and redirected to help supplement bridge funding for scientists considering those indirect costs were brought in by scientists.

Proven or promising external resources or approaches

Many of these problems are systemic and compounding. While paying postdocs more is a strategy, it will take away from research dollars as well as the number of postdoctoral positions. It is only recently that the postdoc structure has been challenged so dramatically. As a result, I am not aware of many changes that have been proven to work. Even the state of Washington has developed a structure to pay postdocs more but the result of this change won't be determined for several years. I would imagine the lopsided pay structure of the administration, to the faculty, to the postdoc, to the student, will have to change.

Response 1635

Perspectives on the postdoc roles and responsibilities

I view the postdoctoral position as a way to augment training and expertise through the lens of what would comprise my ultimate independent research program. For example, as a graduate student I received training in nonhuman primate models. I knew at the time that I wanted my eventual research program to incorporate more rodent models to allow for more experimental manipulations, so I pursued postdoctoral research training in that area. I don't believe that postdoctoral training should be considered perfunctory in terms of getting an eventual faculty position. I believe that graduate students should

identify whether they see gaps in their training or expertise, and if they do, look for a postdoc experience that would incorporate training in those particular areas. I also view the postdoc position as a way to get more supervisory training, e.g. advising more undergraduates and technicians, as well as receiving more training in laboratory management, such as budgeting, mouse colony management, etc.

Fundamental issues and challenges

The current framework for postdoctoral training in terms of expectations, pay, is prohibitive to individuals from marginalized backgrounds. The expectation that postdoctoral training should be obtained at a different institution is an outdated concept, accessible only to those who have the means and lack of familial obligations to move geographic locations for a temporary (~5 year) position. I remained at my home institution for my postdoc because of my spouse's career, and I was frequently reminded that I would be at a disadvantage for funding because I stayed at my home institution. This is in spite of the fact that my postdoctoral training massively augmented my expertise—I went from work doing single unit recordings in awake behaving primates to performing targeted circuit manipulations in rodent models of disease. There is no reason why my training should be considered lesser than, or that I should be viewed as "being afraid of a new challenge" (which is feedback that I had been explicitly given during preparation of fellowship applications) because I made choices based not just on my own aspirations, but the needs of my family.

Even more straightforward: postdocs must be compensated more. Many graduate students I know enjoy laboratory research, but they go to industry because there is higher pay and more job security. As non-academic jobs for PhDs are gain visibility, the postdoc recruitment and retention problem will not go away until compensation can compete with those jobs. As for job security, there should be more of a permanent career track for postdocs. Knowing that there is no permanence to our jobs, no recourse if we get let go, when there are other jobs with higher pay and better job security, of course this will lead to more talented scientists leaving academia behind.

Existing NIH policies, programs, or resources

1. Higher paylines for F31 and K99/R00 fellowships
2. More career level non-K99 fellowships for longer term "senior scientist" type positions
3. Require that any PI receiving NIH funding pay their postdocs the NIH minimum—do not just make it a suggestion or something that is contingent upon an individual fellowship. This is especially critical for institutions that do not have postdoc unions. At my home institution, our postdoctoral association spent over a year trying to negotiate with the institution to set postdoc minimum pay to NIH minimums. After all that negotiation, the institution simply said no. NIH could step in here and make this a requirement
4. To that end, increase R01 budgets so that PIs have the ability to pay postdocs more
5. More transitional awards for postdocs to pursue faculty positions at their current institution. If a postdoc can develop a research program that is independent of their advisor(s) (as in the transition to independence outlined in a K99/R00), there should be no reason why they can't get a position at their current institution.

Proven or promising external resources or approaches

This has mostly been covered above—More job security, higher pay, etc.

In the case of job security, having more oversight over employment rather than the postdoc's direct supervisor would be helpful. Often times, departments have no idea which postdocs even work in which lab, and no one is keeping track of e.g. abusive advisors repeatedly letting postdocs go or otherwise mistreating them.

Response 1636

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

The primary concern that is causing decreased interest in pursuing postdoctoral positions is uncompetitive pay for these positions. Many individuals spend many years in such positions in hopes of them as a launchpad to a faculty position. Following years of even lower pay as grad student, signing on to 2-5+ years of low pay as a postdoc is not a very attractive prospect. Many individuals have to put major life milestones on hold and cannot begin to save for things such as retirement until their 30s-40s due to compensation structures within the realm of academia. Altogether, this makes pursuing a postdoctoral position a financially inviable prospect for most individuals, particularly in light of the salaries available in industry positions.

Existing NIH policies, programs, or resources

There is also hesitancy around staying in academia due to the lack of faculty positions available. Some will tout the comparatively higher salaries of principal investigators/professors as making the years of low pay as a grad student and postdoc as being worth the sacrifice, but securing such a position is far from guaranteed. I am also aware of many people who are interested in remaining in academia, but many not be interested in heading a lab themselves. I believe that additional funding for staff scientist positions for PhDs would allow for upward career mobility within academia, both for those interested in moving up on the ladder prior to securing a position as a principal investigator and those who would be interested in such a position as final career goal.

Proven or promising external resources or approaches

No response

Response 1637

Perspectives on the postdoc roles and responsibilities

I think the postdoc position is a position to further strengthen your scientific resume in academia so that you can start your own lab or become faculty at an institution. The postdoc likely is proposing and managing a research project. They will likely need to teach graduate students in the lab how to operate as a scientist, and will also need to provide a high level of intellectual contribution to the lab.

Fundamental issues and challenges

Honestly the salary is an absolute laughing stock for postdoctoral trainees in academic research. Postdocs and graduate students are being abused financially. The NIH minimum is what institutions give to postdocs which is way too low. Youre asking people who served 6 additional years in a graduate school program making 30-35k a year in a city to then get paid 45k a year for another 5 years. There is no family support, benefits, healthcare etc. That barely covers food and rent. We need support and the salary is being outcompeted.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

Postdocs work alot for little. They also sacrifice a large amount of time without a guarantee for a position.

Response 1638

Perspectives on the postdoc roles and responsibilities

An academic postdoc as I view it should be a constrained (1-2 year maximum) position that aims to launch a well-trained scientist into independence while establishing their niche of choice, whether that be with the goal of an academic position or not. The purpose of the postdoc should be to apply the PhD toolset to a new problem that the individual is excited about, in an environment that is well-suited to launch the individual into that project, which means the project will inevitably have some component that is shared with the lab PI’s domain expertise, though this component should be proportionally smaller than for graduate school trainees.

If postdocs were to be kept between 1-2 years in the life sciences, the limited benefits and pay might be more bearable, however this is not currently the case, as most postdocs go past 4 years. Because of this, the main 2 ways to fix the system as I see it is to shorten the length of a standard postdoc (which will require opening up positions that are non-tenure tack such as staff scientists, project managers, grant writers, etc), or to increase the funding for the current extended postdoc durations, which I view as a shorter term solution that is not sustainable in the current political climate.

Fundamental issues and challenges

Lack of structure, lack of community, low pay, minimal benefits, low job security at the end of it all (partially because they are mostly "Trained" (if you could call it that), with the default mindset of academia. Postdocs suffer from isolation and inflexibility for these reasons.

Further inhibition of recruitment are increasing industry wages along with the ability to do creative science outside of academia. The increasing administrative bloat and scarce funding (which leads to reduced racial/ethnic/gender/sex variability in science as the same privileged people are able to go to the same 8 institutions for the bulk of academic jobs) within academia.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

The whitehead institute's model for postdoc treatment is better than 99% of institutions in terms of pay, benefits, and community for its postdocs. The easiest of these to implement in other institutions is the idea that postdocs can come in as "cohorts" that can attend classes and have regular meetings of their choice, and for this to be mandatory and not opt-in, at least for a fraction of time investments. Something as easy as having to attend a number of seminars or take 1 class a year to keep their postdoc status, for example.

Response 1639

Perspectives on the postdoc roles and responsibilities

Academic postdocs are for continuing training and advancing knowledge to be able to get a job as a PI. Postdocs are integral to the productivity of a lab.

Fundamental issues and challenges

I'm a 4th year Ph.D. student and highly consider not doing a postdoc and going into industry because of the pay. As someone without a lot of external financial support and resources, the gap between academic salaries and industry salaries is becoming too large to ignore, particularly at the postdoc level. Additionally, the requirement of moving for one or more postdocs for a low salary and no relocation funding doesn't make fiscal sense to me. I didn't go into science to get rich, but I thought having an advanced degree wouldn't put me in such a financially precarious position.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1640

Perspectives on the postdoc roles and responsibilities

I view my postdoctoral position as a way to test my independence and creativity as a scientist. For example, my ability to think of my own ideas and execute them as publishable works that will be the foundation of my own lab someday. In my field, the expected time to completion will be 4-6 years.

Fundamental issues and challenges

The most fundamental issue for me, as as woman of child-bearing age and from a low-income background (I am the first to go to college and graduate school), is getting enough income to live in the same city that I work in (Seattle, WA). Similarly aged friends from college who are not in science are buying homes and starting families. I earn just enough to survive, in part subsidized by my partner who left academia to be in industry. I am treading water: I am unable to appreciably save money for retirement, let alone a downpayment for a home. Having a family does not seem possible between my salary and work-life balance limitations. My partner meanwhile is earning 1.7x my salary and works 30 hours a week (with no weekend work). My postdoctoral training is starting to feel like a scam, given that there is no secure promise of a tenure-track academic job following my postdoc. After 12.5 years of intense schooling and training, I am wondering everyday if I should stay in our current academic system. I am starting to pivot to ensure that I have desirable skills for industry science, like computational biology skills. It makes me feel incredibly sad because I am passionate about my research and feel that it can have potential to be transformative for regenerative medicine.

Existing NIH policies, programs, or resources

I am a mid-stage postdoc asking more and more questions to principal investigators in my home department about lab budgeting and how they feel about recent strikes (e.g., in the UC system). They have to continuously write extremely competitive grants (to NIH and others) because funding amount per award has remained stagnant for decades and/or not keeping up with costs of reagents, personnel, equipment, etc. Their research dollar doesn't stretch as much as it used to. Meanwhile, our university soaks up 55.5% of each NIH grant for overhead costs, and yet they don't pay for all of the salary of my PI and keep using delay tactics on union members to prevent negotiation for a more fair working contract. It sounds like PIs will have to foot the bill for salary increases of personnel, which puts even more strain on limited grant dollars, rather than give up some of that 55.5%. I'm unsure if the NIH alone can solve this problem, but from where I'm sitting it sounds like we simply need more money per award.

Proven or promising external resources or approaches

I think the academic system in general needs to compete better with industry: more pay and fairer work-life balance. Right now, it is very costly to stay in a postdoctoral training position. It's hard to feel job satisfaction with extremely low pay while having very expert skills. Some admins around me make much more money than I do, and they don't have a Ph.D. Something is very wrong when managing paperwork pays better than doing transformative science that can create the next new disease therapy or cure.

Response 1641

Perspectives on the postdoc roles and responsibilities

Training following the PhD focused on productivity and stepping up toward an academic or research career.

Fundamental issues and challenges

Low pay. We require post-docs with engineering and computer science skills. Even if new PhDs with these skills are considering academics and research, it is hard for them to resist pay in the tech industry world that is twice or three times what is offered by a post-doc assignment. We currently need 3 post-docs and have none.

Existing NIH policies, programs, or resources

Post-doc pay scales at NIH are 20th century. If the post-doctoral training system is important to the NIH then they must keep up with the times and compete with tech and biotech industry.

Proven or promising external resources or approaches

Possibly industry partnerships that could improve the quality of a post-doc job to be attractive to someone with many options.

Response 1642

Perspectives on the postdoc roles and responsibilities

The post-doctoral period is one of additional training that should encompass: project development, independence, mentoring, and professional development.

Fundamental issues and challenges

Non-academic positions are more and more attractive. PhD students can get a job after graduate school at a starting salary on par with many tenure track Asst. Professor positions, which require at least 5 years of post-doctoral training. It used to be that students pursued academic positions to be able to pursue independent research in their own area, but the difficulties in funding make that often a dream rather than a reality. The continual grant writing and associated stresses are apparent to students, and they don't want it. Add to that the deep and ever-growing levels of administration at most universities, and the term of academic freedom is a relic of the jurassic era.

Existing NIH policies, programs, or resources

Better pay and benefits, better prospects for funding down the road. In addition, limit the amount of salary that can be charged to NIH grants so that medical schools and private research foundations can't use NIH funding to support their investigators. This would force these places to provide appropriate support to faculty, which in turn would make academia more attractive.

Proven or promising external resources or approaches

No response

Response 1643

Perspectives on the postdoc roles and responsibilities

I view a postdoctoral position as additional training, a level above graduate school, to enable independence and prepare an individual to be a PI at a research institution. In the medical field, doctors go through a residency where they have increased independence and care for patients, but have oversight from an attending physician. I believe a postdoctoral position should be similar, with postdocs taking the lead on developing projects and moving ideas forward, with the guiding oversight of a mentor.

Fundamental issues and challenges

The top issue is absolutely financial. Many people leave the world of academia after obtaining a PhD because their talents are valued much more in the private sector. Why would people want to work long hours and weekends just to barely receive a living wage when they can work in an industry setting, get better benefits (like retirement contributions), nearly double the pay, and with a 40 hour work week? The NIH minimum pay for postdocs needs to be much higher, there is no way around it. It's really a simple concept, want to retain postdocs and improve their quality of life? Pay them their market value!

It also does not help that career prospect in academic settings are grim compared to the private sector. There is very little room for growth in academia, with very few tenured track positions becoming available each year. Without the clear space to move up, it is easy to feel stuck and undervalued.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1644

Perspectives on the postdoc roles and responsibilities

Almost free labor.

Fundamental issues and challenges

Low pay. Postdoc salary is unbelievably low and does not provide postdocs a living wage.

Existing NIH policies, programs, or resources

The pay structure must be reconsidered. The accountability of mentors should be measured.

Proven or promising external resources or approaches

No response

Response 1645

Perspectives on the postdoc roles and responsibilities

There are two phases of postdoctoral work; in the initial phase (lasting approximately 2 years), the postdoctoral researcher is expected to generate results and produce publications; in the second phase (lasting approximately 2 years), the postdoctoral researcher is expected to develop their own research program by mentoring students, generating preliminary data, writing grant applications, and providing service to the community (serving on committees, serving as guest editors at journals, chairing conference sessions, etc).

Fundamental issues and challenges

Non-traditional postdoctoral researchers have difficulties obtaining positions in academia at research-intensive universities, despite the potential increase to diversity within these departments. For example, I completed a first postdoctoral research fellowship in a middle-income country abroad and then transitioned to a teaching role at a university nationally. Since it has been >7 years since I graduated, I am no longer eligible for many NIH funding opportunities for postdoctoral researchers. This has led to issues with both recruitment and retention as follows—

Recruitment: During my search for a second post-doc, many faculty at R1 schools did not want to accept me into their labs due to my late-stage and perceived international status. Although I am a citizen, many PIs made assumptions about my nationality and did not want to recruit me to their labs. Furthermore, given the difficulties of completing advanced research projects in middle-income and low-income countries, using standard metrics of success (high impact publications) is not accurate. I believe this to be an issue for many international postdoctoral researchers.

Retention: Fortunately, I was able to find a postdoctoral position at a PUI. However, my current options for securing mentored funding awards are limited by NIH policies that require strong mentorship and facilities that are not always available at PUIs. Therefore, my ability to continue in my position as a postdoctoral researcher is fully dependent on my PI obtaining necessary funding. I believe this to be an issue for postdoctoral researchers across non-R1 universities.

Existing NIH policies, programs, or resources

To aid in recruitment, allowing more opportunities for international postdocs, specifically from low-income and middle-income countries, to apply for funding would increase faculty recruitment of students and postdoctoral researchers who would otherwise not have had the opportunity. Ultimately, any mentored postdoc award could be expanded to include an increase in diversity.

To aid in retention, increasing the opportunity for postdoctoral researchers from PUIs and who have spent time away from postdoctoral research would improve retention of postdocs in these two categories. Here, any mentored postdoc award could be expanded to reduce the impetus on facilities and eliminate the time-based cutoffs.

An additional note on enhancing the postdoctoral experience: I reached out to a program officer, who was dismissive and unsupportive. They indicated that there were no opportunities for my situation and ignored a request for a 15-minute conversation to identify options. Therefore, having designated personnel at the NIH that can help answer post-doc eligibility and guidance questions would greatly improve the postdoc experience with the NIH.

Proven or promising external resources or approaches

No response

Response 1646

Perspectives on the postdoc roles and responsibilities

Postdocs are highly trained workers generating primary data sources for publication, grants, and applications.

Fundamental issues and challenges

Postdocs are not trainees. They are employees that work full time hours, greater than 40 hours a week, and are being heavily exploited.

Existing NIH policies, programs, or resources

You must pay postdocs more money and provide a stable career track.

Proven or promising external resources or approaches

No response

Response 1647

Perspectives on the postdoc roles and responsibilities

Most fields in biology exist to address pressing problems. I gave up seven years of my life and accomplished a lot in that time (more than 20 publications related to my PhD thesis). I regret pursuing postdoctoral study as a means of furthering my education. I should have gone into the industry because I would have made more money and had a better life.

Fundamental issues and challenges

It was the worst choice I could have made, financially and age-wise, to pursue a postdoctoral position.

Existing NIH policies, programs, or resources

You must increase your salary. Doctoral students and postdocs are not indentured servants. They're well into their 30s, at the very least.

Proven or promising external resources or approaches

No response

Response 1648

Perspectives on the postdoc roles and responsibilities

- Gain new experience and professional development/skill acquisition in an area that relates to the PhD's area of study
- Opportunity for protected research time
- Opportunity to develop an independent line of research expertise that is complementary but distinct from the PI

Fundamental issues and challenges

- Salary. Too many talented PhD's are leaving academia for industry because the salary is too low, and not financially viable to continue on (particularly after a long PhD course of study that does not pay well).
- The NIH standard minimum salary is the standard that many locations use to set salary. It is nearly impossible to live on this salary in many cities where biomedical campuses are located, particularly for someone with a highly developed skillset.

Existing NIH policies, programs, or resources

Make the standard entry level salary $70,000. If a PI can't afford this, perhaps they should re-consider if having a post-doc in their lab is right for them.

Proven or promising external resources or approaches

No response

Response 1649

Perspectives on the postdoc roles and responsibilities

In my field, neuropsychology, post doc is required if you want to get board certified in neuropsychology; however, we are able to be licensed and can practice independently after completion of our PhD/internship if we want to forgo board certification. I view this as supplemental training and experience.

Fundamental issues and challenges

The post doc match process and low salary/salary discrepancies make it very difficult if you have a family/children. At this point, we are all in our 30's and have 10+ years of post college training. To have such a low salary at this point compared to faculty/attendings and having to put off family planning is becoming a large rate-limiting factor. Many programs are offering well above the NIH standard salaries (between $60-80k) to help correct for this, but not all programs are able or willing to increase salaries.

Existing NIH policies, programs, or resources

Increase salary or decrease time requirements (e.g., 1 year instead of 2 years for neuropsychology).

Proven or promising external resources or approaches

No response

Response 1650

Perspectives on the postdoc roles and responsibilities

A postdoctoral scientist is in his/her early scientific career. It is a learning process of how to run a lab and an opportunity for self-growth.

Fundamental issues and challenges

The pay scale is the most disheartening situation for a postdoc. With the inflation all around, the salary is still not at par. Some universities do not even pay the NIH scale. The work pressure and expectations are too high when compared to the meagre salary that is been given. This leads to lack of motivation and a stressful life.

There is a gap when a postdoc wants to transfer from academic to industry for the next phase of life. There should be more opportunities to train a postdoc for an industrial job in an academic lab environment.

Existing NIH policies, programs, or resources

Yearly trainings, more travel grants to attend international and national conferences, and payscale.

Proven or promising external resources or approaches

To ensure that the basic postdoc salaries are equal according to seniority levels across the country. All the universities should be following to pay a minimum amount that is set by NIH because even the labs get NIH grants, the postdocs are not paid the amount that is allotted to them and are deprived of their minimum rights.

Response 1651

Perspectives on the postdoc roles and responsibilities

I view the postdoctoral position as training for the next step in my career, but also as a role where I can contribute from the beginning. In graduate school, classes, teaching, and basic lab training take up much of the first 1-2 years, but postdocs can be productive in their first year of training.

Fundamental issues and challenges

Being a postdoc parent is a significant challenge. Although both official policies and informal culture are improving, the default is still to assume that graduate students and postdocs have little to no family responsibilities that might impact their schedule. In my experience, the logistics of taking parental leave were not familiar to either my PI or departmental staff, which contributed to the sense that taking the leave was not expected.

Existing NIH policies, programs, or resources

The NIH childcare supplement is a great program, both to help defray the costs of childcare and to normalize being a parent in academia. I suggest that the program could be expanded by removing the requirement that the money can only be used for licensed daycare, as this is not the only way to incur costs for childcare. In my case, my husband stopped working outside the home to become a stay-at-home parent, which was associated with far greater costs than daycare, but made me ineligible to utilize the childcare supplement granted as part of my fellowship.

Proven or promising external resources or approaches

No response

Response 1652

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

We are severely underpaid—we are highly skilled scientists and the pay rate for postdocs is disrespectful and does not reflect the number of years of education/training we are expected to have for the position. Low pay affects the recruitment of postdocs (especially postdocs of color), retention of postdocs, and our overall quality of life and MUST be addressed.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1653

Perspectives on the postdoc roles and responsibilities

Postdocs are both trainees learning to transition to independence in their research career, and a productive workforce in pushing scientific projects ahead and mentoring in their supervisors' labs.

Fundamental issues and challenges

Unsustainable salaries and benefits

Mentor qualities might help with retention of postdocs, but it's a hit and miss on whether you end up in good support or not —there's no structural protection for postdocs in this regards

Existing NIH policies, programs, or resources

Increase postdoc salaries to 3x an average 1bed1bath apartment in the cities where they do their postdocs

Add matched retirement benefits

When postdocs are funded by the NIH through training grants, universities should be mandated to continue to sponsor health insurance and benefits instead of putting that burden on PIs and the postdocs themselves. It makes no sense that when a postdoc brings indirect money to the university, they lose their benefits as supposed to when they are "university's employers" paid by PI grants.

Proven or promising external resources or approaches

No response

Response 1654

Perspectives on the postdoc roles and responsibilities

I started an academic post-doc with the intention of remaining in academia as a tenure track faculty, but after three years of unsatisfactory mentorship, I have decided to leave academia. I have received inadequate training on how to become a scientific advisor, and the lack of job security contributes to an unsatisfactory and stressful work life.

Fundamental issues and challenges

I am not being paid according to the current NIH standard stipends.so as a postdoc 3 I am now making less money than a postdoc 1 who started this year. The NIH must make it compulsory that PIs should pay their mentees the current NIH standard salaries when funded directly bu NIH grants. This is an especially important issue in retention and job satisfaction of international postdocs who cannot write their own NIH training grants.

Existing NIH policies, programs, or resources

Make it compulsory to pay postdocs at the current NIH standard salary levels. It is unfair that older postdocs are being paid less than newer postdocs.

Proven or promising external resources or approaches

PIs should receive training on management and mentorship. Most PIs are good scientists but terrible mentors. They only care about their bottomline without caring about the postdoc’s career prospects or career development.

Response 1655

Perspectives on the postdoc roles and responsibilities

A post doctoral position is a good opportunity to transition from a student position (PhD) to a permanent position. It represents the opportunity to conduct independently a research project, interact with your mentor and other peers from the field. It is also a good time to be aware of all the paperwork related to administrative, financial responsibilities related to managing your own lab.

In my opinion, post doc trainees should also be responsible to train and mentor students, on short periods.

Post doctoral training represents the opportunity not only to work on your research project but also to think about career in the long term (trainings, meetings, collaborations, funding opportunities.)

Fundamental issues and challenges

The salaries offered for a post doc position are not attractive (on the NIH grids) compared to similar positions in the industry. In most places, this salary does not offer the opportunity to have a decent housing and family life. In some case, having a family life is incompatible: no guarantee for parental leave, salaries are too low to afford child care. The benefits are not attractive, especially when you considerer that many post docs also work during the week end to fulfill their work duties. Moreover, permanent positions academia are very limited.

Existing NIH policies, programs, or resources

Many funding and grants opportunities are limited to US citizens only. As academic research is an international environment, it would be worth to open these funding opportunities to everyone, regardless their citizenship. For example, none of the EU research funding is limited to EU citizens only. Moreover, international post docs already have the burden of the visa, which most of the time are only one year long, and requires to be renew every year (meaning more financial expenses).

Proven or promising external resources or approaches

No response

Response 1656

Perspectives on the postdoc roles and responsibilities

I perceive an academic postdoc as an extended traineeship—a transactional role where you are to provide your services to a heaf of a lab while they occasionally facilitate you learning new things within their realm of expertise, particularly as they pertain to benefitting the lab.

Fundamental issues and challenges

High levels of variability in expectations from heads of lab, combined with "bait-and-switch" tactics make the benefit of a postdoc position volatile. With my 2 postdoctoral mentors so far, the first one promised substantial training in their expertise then treated me as a glorified lab manager, prohibiting my participation in experiments because "nobody else is good at managerial/health and safety/administrative tasks". In addition, the constantly changing workload and leverage that mentors have in coercing postdocs to do tasks that serve only the head of lab's priorities without clearly benefitting the lab itself is start, using leverage of letters of recommendation or contract renewals to achieve these outcomes.

Existing NIH policies, programs, or resources

Some universities to not have an ombudsperson, which can make postdoc advocacy difficult, especially when the university has a vested interest (e.g., financial, prestige, etc) in the faculty member but not the postdoc. Building in explicit conflict resolution plans into F—and T-level grants would greatly benefit the trainees, as would access to an ombudsperson (or similar mediator).

Proven or promising external resources or approaches

No response

Response 1657

Perspectives on the postdoc roles and responsibilities

I view being a postdoctoral fellow as a training period to prepare for the next career step. When describing my role to friends and family outside of academia, I compare it to the "Residency" period for medical students with the caveat that postdocs are optional. From that perspective, the roles of postdocs change based the training goal for each fellow. In my case, I would like to be an independent, academic Principle Investigator. My perceived roles and responsibilities are: conducting science in a field I want to become an expert in, digging into the literature to become an expert in my targeted niche, contributing to peer reviews, assisting my mentor with grant writing, training other laboratory members, and engaging in departmental service. I view my role as a laboratory leader, and someone my mentor is training to be a successful investigator. Therefore, my role is to engage with my mentor in the manner of an apprentice on topics like lab finances, grant funding, being a good collaborator, and networking. However, not all postdocs would have these perceived roles. My labmate is a postdoc whose training goal is to gain a specific skill set prior to transitioning into industry. Thus, their role is to focus on developing and applying their specific technique and engaging in department leadership is not as critical of a training component.

Fundamental issues and challenges

Postdocs are not viewed as valuable resources. We are relatively cheap labor for the extent of expertise and contributions we make to departments. Most postdocs receive the NIH minimum salary and basic university benefits. However, my institution does not match retirement, and our peer institutions do not either. This is a fundamental example of how postdocs are viewed by universities. Full-time lab staff with less experience get this match, but it is not extended to the title of "postdoctoral fellow".

As a postdoctoral fellow at a top 10 funded university, in a department that is historically well respected, I only know 3 postdocs wanting to become faculty. This route has become exhausting due to the low opportunities for funding to transition to the next step. Many universities require independent funding to secure a position, yet opportunities for these are highly stressful and select for a specific profile of applicants. It is incredibly discouraging to see the applicants being invited for university interviews and match that many have top tier publications and K99/R00s. The productivity needed to achieve these things in the short period of time given to postdocs does not accommodate for families or disabilities.

Existing NIH policies, programs, or resources

The NIH could make it mandatory for universities to match BENEFITS as well as salary. Institutions wishing to hire postdocs must give them the same package as staff. Additionally, the NIH could extend the eligibility window for postdocs to apply for funding. The five year crunch for K99s and K22s is exhausting. I would be less stressed and more happy in my position if I had the time to develop top tier papers—and had the financial resources from my university to do this without tanking my retirement or family savings. I love the time-period of being a postdocs, but the system is designed to be highly stressful and degrading.

Proven or promising external resources or approaches

I feel confident that talking directly to postdocs and graduate students—not their universities—will reflect the sentiment of low tolerance for the high stress/low perceived value that is endemic to the current postdoc experience.

Response 1658

Perspectives on the postdoc roles and responsibilities

I personally believe a postdoc, especially in the early stages of his/her career, should be considered as a trainee, requiring minimal supervision at first. In their latest stages, postdocs can supervise junior trainees, including students and technicians. Postdocs must attend seminars, give lectures and minimal teaching, present at research conferences and meetings. Preparing manuscripts for submission, as well as writing grants is a must, especially if they plan to continue working in academia.

Fundamental issues and challenges

The fundamental issue (which has been partially addressed) in recruiting and retaining postdocs is the harsh competition with industry. Nowadays postdocs look for job security, better pays and improved work-life balance. I understand that applying a 4-hr/week schedule to postdocs does not make sense, but we need to improve their work-life balance in some way, so that they don't feel underpaid work force. Retention at academia can be achieved by providing easier career paths and facilitating the path to independence (maybe increase the number of K99/R00 awards every year?)

Existing NIH policies, programs, or resources

K99/R00 is excessively competitive as of now and the limited number of awards makes it almost impossible to achieve. Furthermore, nowadays NIH reviewers tend to consider a K99/R00 potential awardee as someone who comes from a famous institution and has published on high IF journals (e.g. Nature, Science, Cell.), which not always completely reflects the quality of the applicant (indeed, publishing on Nature often reflects the ability of the mentor, rather than the postdoc.).

Proven or promising external resources or approaches

Postdoc salaries should be adjusted based on cost of living. For example, postdocs in NY, California or Colorado should receive higher salaries. More training opportunities should be available, along with institutional (or NIH) funds to facilitate trainings.

Response 1659

Perspectives on the postdoc roles and responsibilities

I view this position as an apprenticeship. The role is to conduct independent research under the guidance of a primary mentor and a mentor team, and to develop skills required for the desired research position in academia, government or industry. This should include training in experimental protocols and bioinformatics, presentations and networking at scientific conferences, grant writing, and mentoring students. Responsibilities include publishing high quality manuscripts, working as a member of the lab, leadership within the lab and in desired scientific societies or networks, and working with the mentor to develop a career plan to achieve the desired job.

Fundamental issues and challenges

Postdoctoral fellows are dependent on NIH grants not only for salary, but also for supplies and reagents. Thus, increasing salaries without increasing the overall modular budget can hurt the postdoc in limiting

funds available for experiments, travel and publication. One fundamental issue is the limited opportunities for foreign scientists to apply for NIH grants, beyond the K99. Obtaining independent grant support can make the postdoc more competitive for the job market, and more independent in directing resources for their training. Postdocs should be able to apply for supplements that can help offset the exorbitant costs of daycare. The cost of living can also vary a great deal across different cities in the US. PhD level staff scientist positions in academia would greatly expand opportunities for postdocs wishing to continue in academia.

Existing NIH policies, programs, or resources

Expanding opportunities for foreign postdocs to apply for NIH grants would be very helpful. A mechanism to connect postdoc candidates with interests in particular fields with NIH funds scientists would also be helpful. A mechanism for postdocs to apply for travel grant support would be valuable for allowing them to attend scientific conferences and to network. NIH sponsored career fairs would allow postdocs to learn about different job opportunities and career tracks. The low NIH grant funding lines are very discouraging to both students and postdocs, and lead many students to pursue an industry position rather than academia. I think study section reviewers could use more training, and I think the R35 NIGMS mechanism for junior scientists is a great way to encourage creative, new approaches and research.

Proven or promising external resources or approaches

I think institutes and Universities could invest more in supporting postdocs including supplements for childcare and housing. I think they should also provide opportunities to supplement salaries through teaching, service on committees, peer review, editorial services, formal mentoring, workshop organization and service on thesis committees. This way the postdoc's salary would not need to be fully supported on the NIH grant, and would expand opportunities to tailor training and experiences for a specific career track. Perhaps scientific journals could pay postdocs for reviewing publications. Excessive "unpaid" labor in academia has long been a problem but is particularly difficult for postdocs who make less salary than faculty.

Response 1660

Perspectives on the postdoc roles and responsibilities

Postdoctoral training is the path to independence and a way for a Ph.D. recipient to gain know-how to mentor, teach, and do high-impact research.

Fundamental issues and challenges

Low salary and more work hour expectations.

Job and visa insecurity

Low insurance and health care coverage for international applicants.

Academic bullying and protection of the PIs by institutions

Existing NIH policies, programs, or resources

Please enforce strict norms for a good pay grade. We are not just underpaid, we are too underpaid. Each program should enforce that if there are postdocs employed through grants, the PIs will ensure that they strictly adhere to work hours and pay the employees well. If the PIs on NIH grants are caught by whistle-blower policy bullying, their NIH grant to carry out research would be terminated. The money used to support grad students and postdocs will, however remain effective till the grant ends!

Proven or promising external resources or approaches

No response

Response 1661

Perspectives on the postdoc roles and responsibilities

The postdoctoral position is ideally an opportunity to obtain additional training on grantsmanship, publication, and training related to research activities. I view it favorably. It would be a great opportunity to further develop my research skills and focus on publications.

Fundamental issues and challenges

The biggest barrier to me completing postdoctoral training is the low pay. I've spent the last five years on a very small monthly stipend, which only covers my mortgage (not childcare, health insurance premiums, or food). I can't afford to make half of what an assistant professor would make for 2, 3, or 4 more years, especially because my student loans will need to be paid 6 months after graduating. I also can't afford to relocate with my family, as my partner's job is located in one place. Additionally, the postdoctoral training opportunities that I've searched for are working on someone else's project, which isn't related to mine. There are not postdoctoral opportunities in my field of study. I wouldn't be able to maintain immersion in the literature while working on someone else's project. The postdoctoral opportunities I've looked at range from 2-4 years. I can't imagine working on someone else's research for 4 years just to get a faculty position.

Existing NIH policies, programs, or resources

The pay should be increased to at least $80,000 per year, but should be adjusted for the location. High cost of living areas would be challenging to live in on $80,000 a year, while $80,000 would be appropriate in low cost of living areas. Additionally, postdoctoral opportunities should allow trainees to explore their own research while also helping with other faculty projects.

Proven or promising external resources or approaches

No response

Response 1662

Perspectives on the postdoc roles and responsibilities

A postdoc should be a training position that provides the individual the opportunity of lead research projects independently at the time at the time it provides the chances to get familiar with other relevant skills required to become a Principal Investigator. Some of these additional skills are grant writing, mentorship, budget preparation, and IRB documentation.

Fundamental issues and challenges

One of the main issues on the recruitment and retention of postdoctoral candidates in academia, is that the economic compensation is not up to the assigned responsibilities and current cost of life. A postdoc salary can barely support a family, while the postdoc is expected to lead a research project, to mentor undergrad and grad students, write grants, articles, all of it at the same time it is expected for him to train to become and independent PI. In the last stages, an additional activity is to look for work positions, which is also time consuming.

The postdoc position should provide from the start a clear path of professional development. If the working environment fails to truly prepare and guide the postdoc through this transitory position into a research independence position, the postdoc will lack motivation to endure the hardships and under-compensation.

Mentors for postdocs should be regularly audited in terms of success of their mentees, drop-outs, and productivities so that toxic environments can be identified and corrected.

Existing NIH policies, programs, or resources

Expand and complement programs oriented towards the transition from postdoc to independent PI such as K99/R00 would provide the postdocs with motivation and a clear path to independence.

Proven or promising external resources or approaches

Improve salaries and benefit packs for postdocs to a level that honors the relevance of the postdoctoral position in the research enterprise, that corresponds to the stakes and responsibilities, and allow family planning.

Response 1663

Perspectives on the postdoc roles and responsibilities

I view it as time to develop a plan for an independent research career. I work in informatics and have my own datasets. This position makes me more independent than peers who are reliant on a mentor to provide them with guidance and are more tied to their lab/productivity. However the way academia is organized, the lack of a mentor doing exactly what I do feels like a setback as well.

Fundamental issues and challenges

The dichotomy between needing to be in a lab and focusing on your mentor's needs, while developing your own unique ideas and identity, seem impossible to navigate in a two year span. I do think this impacts retention significantly, and for most post-docs, increases their workload and decreases their quality of life as they essentially do two jobs at once.

Existing NIH policies, programs, or resources

More NIH-issued coursework would be appreciated since there is so much variability in T32 curriculums. I also think there are important missing conversations about how industry interacts with NIH—if NIH takes control of this narrative and teaches its trainees how to proceed in this realm, it feels like more of a symbiosis rather than a conflict of interest that impacts retention negatively.

Proven or promising external resources or approaches

No response

Response 1664

Perspectives on the postdoc roles and responsibilities

Post-Doctoral position means—learning how to manage a lab, how to write a grant or article and learning to be a PI. Nonetheless, somethings not improve in a lab where you are micromanaged, although, PI supports you for your grants and writing articles. Additionally, post-doc should be a person that could effectively run a project with minimal guidance from his/her PI. Sometimes, it is possible only when a PI and lab has enough trust on that post-doc.

Fundamental issues and challenges

Issues: Work-life balance—unable balance these two because of work load or some other profession issues including professional miscommunication with colleagues.

Salary: it is too low to spend good time with family after working for several extra hours

Recruitment and retention: because of the university rules to give one year extension, it was difficult to focus on work when the visa is coming to an end

Quality of life: I did not go to India for like 3.6 years, because visa restrictions and money issues

Existing NIH policies, programs, or resources

One thing that could be modified is—salaries for post-docs, it should be minimum reasonable amount

VISA: visa should be provided for like 5 years therefore post-doc can have chance to go to their home country and visit their family

Proven or promising external resources or approaches

Above things should help to improve this section

Response 1665

Perspectives on the postdoc roles and responsibilities

The postdoc is position that allows a researcher to pursue additional training to become more qualified for a faculty or senior scientist position. It gives one the chance to fill any training gaps, switch or merge fields, learn new techniques, pursue projects more independently, do more mentorship, learn more managerial skills, improve writing skills etc.

Fundamental issues and challenges

1. Yes, low salaries and benefits, but there's much more.
2. Poor mentorship & training.
3. Poor job prospects. Most postdocs aim for faculty positions but most of these are given to those from a very small number of universities (and typically large labs that easily put smaller labs at a disadvantage). This makes the job market incredibly competitive, and biased.
4. Overworked, as postdocs we often work multiple extra jobs, we fill-in for the busy PI, serve as lab managers, technicians, writers, mentors, etc. This generally goes unnoticed and taken for granted even though it generates poor work-life balance.

Overall, I believe the top reasons making postdocs leave academia are issues 2 and 3 above, issue 1 if a minority.

Existing NIH policies, programs, or resources

1. Increase pay and benefits—postdocs are research scientists and should be compensated as such. One option is to increase the modular R01 and perhaps to encourage institutional support.
2. PIs should be held accountable for the quality of training a postdoc receives. At the same time, PIs should be incentivized to provide good training and mentorship.
3. Provide additional funding opportunities to post-docs. For example, extend T32 and F32 eligibility/funding or provide funding opportunities that fill the gap between these and a K99/R00, or provide more transitional grants that start earlier than a K99.
4. NIH should advocate supporting professional staff, such as project/research scientists, especially in labs where the PI does not have the bandwidth to provide good training/mentorship and to cope with the limited number of faculty positions available.

Proven or promising external resources or approaches

Not really, but this article starts with a good analogy:
https://www.insidehighered.com/advice/2023/01/24/research-university-needs-professionalization-opinion

Response 1666

Perspectives on the postdoc roles and responsibilities

Necessary post-graduate training that allows focus (similar to post medical school residency) on specific projects. In the past few decades the postdoc training period has increased from 3-4 years to 6-10 years which is too long for someone to be in that position.

Fundamental issues and challenges

In order for the US to remain competitive in biomedical research, postdoc salaries should be increased 30-40% over current standards and PIs, granting agencies, institutions, etc. should encourage postdoc training to last about 4 years and after that time should transition to research scientist position with higher pay and more responsibility (ability to acquire independent funding if desired). Postdocs should have significant benefits including health care, dental care, and retirement savings programs so that time lost in training does not result in lost time accruing savings over a career.

Existing NIH policies, programs, or resources

Postdoc salary scales should be increased and grant budgets should be increased to cover those costs. For example, the standard NIH RO1 modular budget has not changed in decades and likely needs to be increased from $250,000/year to at least $350,000/year to accommodate personal salaries.

Proven or promising external resources or approaches

NIH should hold public meetings to discuss future of postdoc training. Do we want to keep training postdocs for too few academic principal investigator positions or should the training be specific to industry or academia? Would it make sense for institutions to have many more independent PIs with small labs or few PIs with very large labs? Currently, the system only rewards those with very large labs as small labs struggle to maintain funding and personnel. The funding cycle is so short that most PIs spend 50% time writing grants rather than concentrating on science and mentoring trainees which seems counter productive. This will likely squelch innovation and breakthroughs as scientists need time and freedom to explore different avenues.

Response 1667

Perspectives on the postdoc roles and responsibilities

I worked in the scientific world for most of my career (NOAA, WA State Dept of Ecology) and now have my own training company (Cathy Angell Communications). I've had the opportunity to train many Fellows around the country who work for federal and state agencies, as well as science-based non-profits. These individuals are often in positions where they need to speak to other scientists, agency staff, conference attendees, and to the public. Their presentations are often ineffective because they are modeling the way that they've seen other scientists give presentations (slides filled with bullet points, graphs that the audience may not be able to easily interpret, way too much focus on "their process" as opposed to what the audience is interested in or how they best take in information).

Fundamental issues and challenges

No response

Existing NIH policies, programs, or resources

I believe that offering excellent science communication training to postdocs is critical. We live in a world with complex environmental issues (and misinformation!) that need to be clearly communicated. There are many excellent trainers in different parts of the country.

Proven or promising external resources or approaches

There are organizations and institutions made up of people who focus on clear science communication, such as the Association of Science Communicators (https://www.associationofsciencecommunicators.org) and The Science Communication Network (https://sciencecommunicationnetwork.org).

I offer training (virtually and in-person) to institutions and agencies in the United States that help scientists and public officials present their research and projects in a way that people can easily understand. I help them develop clear messages, create effective slides that keep people engaged, and present information in a way that sticks in people's brains. After one of my trainings, a graduate fellow stood up and said "If I had taken this training in graduate school, it would have changed my life." Alex Rosen, former Sea Grant Fellow working at the WA State Dept of Ecology). I think that the NIH could make a massive impact on how science is communicated by supporting science communication training for postdocs.

Thank you for the opportunity to offer feedback.

Response 1668

Perspectives on the postdoc roles and responsibilities

It seems a postdoc position is marketed as an additional training opportunity. However, as a current PhD candidate, it feels like a postdoc is a poorly paid position designed to keep cheap labor in academia. After earning the highest academic degree possible while earning minimal wages for multiple years, we are then expected to take an additional 2-3 years earning minimal pay which is not commensurate with cost of

living in many areas of the country. And a postdoc by design has no job security, so I would have to relocate for a postdoc to then have to relocate again for a job that may or may not be available when I finish postdoc training.

Fundamental issues and challenges

Low pay for someone who just earned a doctoral degree, lack of ability to direct your own line of research (i.e., moving the PI's research line forward), lack of independence, no job security or promise of a job upon completing postdoc training.

Existing NIH policies, programs, or resources

Paying postdocs what they are worth would be the first step. We are not research assistants or graduate students. We are professionals who have earned the highest academic degree and paying us to reflect that is the first change that needs to happen. Also assisting with job placements after finishing a postdoc position would help make a postdoc position more appealing.

Proven or promising external resources or approaches

Making this an opportunity that actually helps postdocs establish their own line of research rather than being cheap labor to advance the PI's research.

Response 1669

Perspectives on the postdoc roles and responsibilities

A job in academia that requires me to conduct research, analyze data, acquire funding and mentor graduate students.

Fundamental issues and challenges

Expectation of the performance of a trained professional while paying the salary of a trainee. Results in poor personal and professional quality of life.

Existing NIH policies, programs, or resources

The NIH mandated payscale for postdocs should be a minimum of 65K p.a starting.

Good institution covered health insurance and retirement benefits with institution contribution should be mandatory.

Postdocs should be allowed to be co-PIs on grants with their mentors. Several institutions do not allow this and this severely hampers a postdoc's prospects of a career in academia. True especially for international postdocs who have only the K99 as a career grant option.

Proven or promising external resources or approaches

Higher pay.

Better benefits including parental leave.

Career development opportunities like grant writing, industry collaborations, teaching opportunities etc.

Response 1670

Perspectives on the postdoc roles and responsibilities

Postdoctoral are highly skilled workers and thus, although part of an academic is training in nature, overall, postdocs are the major contributors to skilled academic research and should be compensated as such. Academic research would stall without the contributions made by postdoctoral research. Postdoctoral researchers contribute their skilled labor and are the major drivers of intellectual progress in academic labs. Postdoctoral researchers are often responsible for training junior scientists, and thus are the major contributors to future scientific endeavors, as well.

Fundamental issues and challenges

The major issue inhibiting recruitment, retention, and overall quality of life is the NIH's policies limiting the maximum postdoctoral salaries. Postdocs are highly skilled workers and deserve to be compensated as

such. As a senior graduate student considering an academic postdoc, I have chosen not to pursue an academic postdoc solely due to the lost wage potential and inability to support myself and my family in the current climate. Another major issue is the viewpoint that postdoctoral researchers are "trainees." This is a misconception that allows for the mistreatment of postdoctoral researchers under the guide of providing training opportunities.

Existing NIH policies, programs, or resources

Remove the salary maximums and allow grantees to request more funding to pay postdoctoral researchers their market value.

Proven or promising external resources or approaches

No response

Response 1671

Perspectives on the postdoc roles and responsibilities

Academic postdoc is a critical training period for people who are enthusiastic in a career as principle investigators in an academic environment or to gain experience in leading research projects and managing funding. Postdocs are also the more productive workforce in a research lab compared to other graduate and undergraduate trainees, and contribute to the research diversity of a given lab by bringing in new ideas and technologies from their graduate experience.

Fundamental issues and challenges

The low income of academic postdocs in comparison to industry research scientists with comparable experience level is a huge hurdle for choosing this career path. Postdoctoral years coincide with the phase in life when people are raising young children or purchasing homes, both of which are extremely challenging or nearly impossible with a postdoc salary, especially in cities with high living cost. As a result, postdoc career path may be only appealing to people who are enthusiastic about starting their own labs, and only feasible to those who don't have any financial pressure.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1672

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

Compensation is the largest hurdle in recruiting and retaining postdocs. Especially at institutions in areas with higher costs of living, the pay is insufficient to cover living expenses. While pharma has always had it's influence in drawing from the doctoral talent pool, the growth from the tech industry has been accelerating in recent years. As our methods and techniques have advanced, we have moved away from simple linear and logistic regressions to utilizing machine learning and big data. This skill set is highly sought after in the tech sector, especially as they are beginning to recognize the value in having subject knowledge as opposed to technical knowledge. These companies provide 3-4x the compensation of a postdoc position. Coupled with the increasingly competitive funding environment, and the transitionary period that many postdocs face with considerations to starting a family, the financial burden of receiving less pay for 3-5 years in hopes of securing a faculty position become untenable. Similar to the debates that have been ongoing surrounding minimum wage, the pace at which federal agencies operate make it difficult to keep up with the rapidly changing job environment that is being offered from industry.

Existing NIH policies, programs, or resources

Proven or promising external resources or approaches

No response

Response 1673

Perspectives on the postdoc roles and responsibilities

I came to the US with 2 different fellowships for my postdoctoral phase to work at an Ivy league university in Boston. I am very dedicated and want to become a professor in my field and have never considered any other job. It was always my dream to have my own laboratory. A postdoctoral researcher who comes with it's own money should be able to focus on science 100% of the time to produce the best possible scientific output and ultimately improve the life and health of humans. A postdoc should be willing and able to work over 80h and not shy to go to the laboratory on weekends. It is a dedication and decision for life.

Fundamental issues and challenges

After living in Boston for 1 year with a J2 dependent (who is not getting any job because no green card) I am about to reconsider my career path which is very painful to me. The financial situation becomes unbearable which several recent articles in scientific journals clearly illustrate. Postdoc salaries get evaluated by people that are not in postdoc shoes and are unable to judge the hardship postdocs face. In particular when living in cities like Boston, San Francisco or New York city. Rent is eating up over 60% of the income and without a spouse working even going to the dentist causes existential anxiety. It is clear to me that industry positions will always be paid better than academic ones but they are currently 3-4x as high as the NIH postdoc recommendation which illustrates a severe imbalance. It is impossible to have a family since the money is clearly not even enough for 2 persons. A postdoc is highly educated (>20 years of education) and still kept at a trainee salary whereas industry appreciates postdocs as fully educated and valuable scientists. In my opinion salary is clearly and almost exclusively the reason so many postdocs leave academia. Other reasons which make up a much smaller fraction why postdocs leave is the job insecurity and flexibility that is expected leaving people in their 30's with a very insecure future. Even moving to the USA as an outsider one faces usually a broker fee, 2x rent, a security deposit and expensive visa and junk fees that have to be paid excluding many people to come. Usually PI's are not willing under any circumstances to pay a welcome bonus, any financial support or help with housing. Furthermore, foreign fellowships are getting decreased by fringe benefits from the employing institutions.

Existing NIH policies, programs, or resources

Postdoc salary pay scales have to be adapted to the living costs in the institutions place. A yearly salary of 60k will guarantee for a good life in Texas whereas in Boston or San Francisco it is below the poverty level. I personally see no other resort than the NIH forcing PI's to pay higher salaries to postdocs because almost nobody will be willing to increase by themselves. In particular in Ivy league institutions this is a big problem. Higher RO1 grants will most likely result in higher overhead fees that are not controlled at all and in some places will make up >70% of grants and it likely will improve the salaries of administratives only. (Almost every administrative at a US university gets paid significantly more than postdocs despite much lower education requirements). Allowing a maximum overhead fee for an RO1 would guarantee that the money which is intended to be spent on science can actually be used for scientific research. Foreign postdocs usually have no coverage of healthcare which when paid private is unaffordable for any foreign fellowship holders. Requirements for guaranteed healthcare that gets supplemented by labs that are funded by RO1 holders would include several foreign postdocs that are willing to come if they can afford it. Fringe benefits on fellowships should be controlled and ideally inhibited by the government. Tax treaties exist for some foreign scientists whereas some nations are excluded from such benefits. A way to allow equal access to postdoctoral positions would be NIH supported tax cuts for postdoctoral researchers to avoid financial hardship.

https://www.science.org/content/blog-post/time-fix-trainee-salaries

Response 1674

Perspectives on the postdoc roles and responsibilities

Physicians rarely have dedicated time to participate in research during their clinical training years. Postdoctoral fellowships create an opportunity for physicians to dedicate time to research and develop a research career.

Fundamental issues and challenges

Postdoctoral research fellowship salaries are not competitive or sufficient for individuals navigating their careers with families and/or greater burden of educational loans. For instance, I am a physician researcher currently in my seventh year of postgraduate training and I do per diem clinical work, up to 70 hours per month, to ensure that I can afford rent, other living expenses, and make payments towards my educational loans (original principal balance over $300,000). This is an additional 17.5 hours per week, or 57.5 hours weekly if assuming 40-hour work week in the postdoctoral fellowship, although, hours for research are often more than 40hours/week and near 60 hours if one is productive and writing regularly. That is a nearly 80-hour work week. I am able to do this for now, but I also am single and have no dependents and associated costs to cover. In general, there are significant opportunity costs for participating in a postdoctoral research fellowship. The promise of success in research is also statistically low with few individuals receiving independent research funding to support continued careers in research. So, even if you decide to make sacrifices to participate in a postdoctoral research fellowship, you may not be able to continue in research even with the most valiant efforts and 80-hour work weeks. Thus, most people decide other careers, or research in other areas like pharmaceutical industries that can provide reasonable salaries and benefits, and the potential for advancement and continued careers in research.

Existing NIH policies, programs, or resources

1. Ensure adequate salaries and adjust to costs of living
2. Ensure adequate health insurance and other benefits (including long-term disability insurance)
3. Paid family and medical leave (my current program does not have paid family or medical leave so individuals serious about starting families are not going to complete the postdoctoral research fellowship; or if medical ailments occur then are likely to leave fellowship)
4. More funding for conferences and travel to participate in these (currently, our fellowship provides up to $1000 per year for educational and conference expenses which is not enough to even attend one conference (registration fees, travel, hotel expenses exceed $1000)
5. Create system to routinely review current postdoctoral research fellowships (even if low-resource review such as individuals submitting annual surveys anonymously to an NIH workgroup for postdoctoral fellowships)

Proven or promising external resources or approaches

Without adequate salaries and benefits, most individuals (unless from privileged backgrounds +/— adequate financial supports) will not pursue these training opportunities, no matter how passionate they are about research. So, first step is to make sure that institutions with T32 grants are actually providing reasonable salaries for trainees to live on in their respective region. This would mean less outside work and more time for research, and ultimately better quality of life for trainees. Additionally, as a current NIH LRP awardee, there are improvements that could be made to this program. The amount awarded is considered earned income, and although NIH pays the IRS federal taxes on this amount, the awardee is still responsible for the state and city taxes along with potentially moving into a higher tax bracket without the actual "earned income" to save for estimated taxes. So individuals then must come up with additional monies, i.e., work more, to even maintain the NIH LRP and balance costs. Even though this award is meant to encourage research and keep individuals from underserved backgrounds in research, it ultimately means more outside work, less time for research, and possibility of not being able to pay overall taxes in highly taxed cities. This could be changed by making it that all taxes are covered by NIH LRP OR that some of this funding is directly transferred to the awardee (not just Loan Server) so that they can save these monies for taxes from this "earned income."

Response 1675

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

For postdocs living in big metropolitan areas te cost of living is such that rent easily repetresents 50% of our net income. Salaries should be supplemented in order to decrease rent burden.

Existing NIH policies, programs, or resources

Response 1676

Perspectives on the postdoc roles and responsibilities

I completed by postdoc several months ago, and my postdoc lasted about 2 years (in a T32 program). I saw that time as an opportunity to prepare myself to be a strong candidate for an academic tenure track career, publish my dissertation papers, work on new research, and to increase my first-authored publications. I also viewed it as a time to expand my network and refine which direction I wanted my research career to go in. I wanted to come up with my 5-to-10-year plan, and to find a niche for myself. I was able to find a postdoc specifically for underrepresented minority scientists, and I qualified because I have a long-standing disability. The post-doc experience was structured so that I would have a primary mentor, a secondary mentor, and a peer-mentor. It helped to have a lot of support, but ultimately, I felt like I was still left unprepared for securing independent funding and finding an academic position outside of the institution where I did my postdoc. There very also very limited options for faculty positions internally, and individuals with my skillset were not the priority. I worked on multiple specific-aims pages for potential funding ideas, but not seemed to be feasible for the type of funding provided to early career investigators and to facilitate the transition to a faculty position.

Fundamental issues and challenges

As a former postdoc, I think the biggest issue with NIH funded, extramural postdocs is the low stipends, and limited benefits/time-off. The stipend does not account for the differences in the cost of living across the country. The stipend doesn't go very far in places like NYC. RAs and program coordinators with only bachelors' or masters' degrees were making much more than I was with a PhD, while being part of the same research team, during my postdoc.

The postdoc was stressful, because there is a lot of uncertainty about where in the country, I would be able to find a job. There are very few openings in academia for public health social and behavioral researchers. Because of the uncertainty, low pay, and limited benefits, I couldn't afford to "start my adult life" . I had to delay having children. I had the option to extend my 2-year postdoc for at least another year, but I decided against it. Instead, I took a position in an administrative/analyst role at the NIH. While in the long run I won't get to do the type of research I wanted, I make nearly twice as much now. I was able to move, buy a house, and start a family. If the pay for the postdoc was better, and there was a higher probability of securing a permanent job in academia, I would have stayed. Staying would have been a better use of my skillset and would have been more intellectually fulfilling. If there were better funding mechanisms to transition from a postdoc to a tenure track faculty position, I would have also stayed. However, the K99/R01 mechanism is so competitive, the chance to get an award are low. I have seen colleagues rejected multiple times.

Existing NIH policies, programs, or resources

To enhance the postdoc experience, NIH needs to provider much larger stipends that are adjusted for the cost of living of the location where the postdoctoral training is taking place. There is a need for better sick leave, vacation days, and family leave benefits. Otherwise, postdoctoral fellows/scholars, especially those from low-income backgrounds, have little incentive to apply or to stay (be retained) in these postdoctoral programs. Otherwise, people with excellent training and high potential are going to leave academia. That

is why I left. There are also very few options to secure an academic tenure track position. Universities want to see that you will bring in funding, but there are very few NIH funding mechanisms that help facilitate the transition from a postdoc program in one institution to a faculty position in a different institution. The K99/R00 mechanism is super competitive and not a viable option for everyone. It can extend a postdoc longer than necessary.

There also need to be more centralized resources for helping doctoral students find postdoctoral training opportunities, especially for underrepresented scientists and individuals with disabilities. Programs should also be required to provide high quality mentorship. I am lucky that I had great mentors. I really appreciate that NIH has the T32 programs. I think it would be great if there were more T32 programs in U.S. and if the stipends were higher.

Proven or promising external resources or approaches

No response

Response 1677

Perspectives on the postdoc roles and responsibilities

To me, a postdoc means a short-term research position that provides further training in a particular field, and for individuals planning research careers in academia, government, or industry, the postdoc years can be an opportunity to develop independence, hone technical skills, and focus research interests. Postdoc is normally a bridge between completing a Ph.D. and pursuing a career in academia, but you can also do a PostDoc to gain further skills and training for other careers.

Fundamental issues and challenges

1. The National Research Service Awards (NRSA) stipend guide for specific National Institutes of Health (NIH) training programs such as T32s and F32s serves as a de facto minimum postdoc salary paid at most research institutions in the United States7. This salary scale ignores the staggering discrepancies in the cost of living in different geographical regions. For example, in a two-person employed household in Boston's Suffolk County, the annual living wage for a single individual has been estimated at $71,869 before taxes, which rises to $111,259 with one child and $148,148 with two children. These wages include only necessities such as housing, healthcare, childcare, transportation, food, and civil costs. Yet the NIH de facto postdoc stipend for someone starting a postdoc in 2022-2023 is $54,840 a year. The NIH must be aware of this issue, as it pays its own intramural postdocs more. The starting 2022-2023 salary for intramural postdocs is $57,400-$64,000.
2. Besides inadequate monetary compensation, the lack of support for childcare, housing, healthcare and matched retirement makes academic careers less sustainable for postdocs. As per the National Postdoctoral Association's institutional policy report for 2021, basic insurance plans are provided to most postdocs. However, other significant benefits such as matched retirement, tax-deferred retirement, flexible spending account, subsidized childcare and long-term disability are poor.
3. Limited job availability may discourage individuals from investing in low-paid postdoc training if the chances of obtaining full-time positions that reward this training are slim.

Existing NIH policies, programs, or resources

1. Raise postdoc salaries annually in line with inflation;
2. Revise postdoc salaries with a cost-of-living adjustment based on geographical regions; and
3. Reveal transparent policies for postdoc salaries and benefits in institutions and granting agencies.

Response 1678

Perspectives on the postdoc roles and responsibilities

The post-doctoral position should serve as a way to transition from trainee to independent scientist ready to run their own lab or contribute to scientific work as a senior scientist

Fundamental issues and challenges

Postdoctoral positions are often used as a way to recruit skilled laborers at a cost which undervalues their technical and knowledge area expertise. Graduate students often won't choose postdoc positions when they can take jobs which pay them in line with their worth. In addition, the lack of job stability and uncertainty of advancement in the career means that it is less of an option. Also, many postdoc fellowships create issues financially due to the differences in taxation, and lack of full employment which often removes insurance and other benefits traditional jobs offer.

Existing NIH policies, programs, or resources

Response 1679

Perspectives on the postdoc roles and responsibilities

There is actually very little need for American PhDs, who already have 5-7 years training, to do a post-doc for additional 'training' at all. This is especially true for those going on to industry, where the vast majority of PhDs will go. The only real reason for an academic post-doc is to get additional publications to be competitive for tenure-track positions.

The reliance on post-doctoral labor needs to be vastly reduced and replaced with long-term academic scientists. The post-doctoral positions that do exist should be reserved for PhDs looking to be academic-track researchers or faculty. The goal should be for as much autonomy and independence as possible. Faculty working closely with post-docs should be considered senior 'collaborators' not mentors. 'Mentorship' necessarily limits what the post-doc can intellectually take credit for and what projects they can take with them to future work. To allow for more independence it might be helpful for Universities to have shared lab spaces with general resources that *independent* post-docs and researchers can use for their work.

Perhaps someday in the future, it will be departments, not individual labs that will choose promising post-doc candidates, just as they would graduate students or faculty. This would mean that only the most-promising candidates are accepted, that they have the ability to move independently between labs and collaborators as they see fit, but they can have some protected time to develop their work as independent, autonomous individuals.

Fundamental issues and challenges

No one wants to be in a low-paid 'training' job all their life where they have very limited personal rights and autonomy! But, pay is actually only a fraction of the problem, as many of us love doing basic science in spite of not getting paid enough! Another major issue is that post-docs have no rights, autonomy or

system for independent review and problem-solving without severe career repercussions. Post-docs are forced to be in a powerless 'mentee' role whether they need it or not. The lab PI can determine literally everything about the personal and professional rights people in the lab have, who gets which opportunities, what sort of recommendations are written and who gets credit for what work. The tenure system further encourages this unequal dynamic as tenured professors bringing in money have the feeling they have earned the right to manage their lab however they see fit, appropriate or not. While graduate students at least have a committee to consult, post-docs have literally no one aside from their PI. It is hard for me to understand how this microcosm of feudalism can exist within a democratic country among scientists who value peer-review, debate and diverse expertise to make decisions on scientific papers, but not on people's individual rights, intellectual autonomy and careers!

Another key issue is how funding decisions are made based primarily on first-and senior authorship, which disincentivizes teamwork and collaboration, while encouraging intense interpersonal competition. This ultimately limits the quality of science that can be done, the diversity of people and ideas involved and creates a working environment that many of the most creative people are uncomfortable working in.

Existing NIH policies, programs, or resources

More high-level academic research scientists would mean higher quality work, more repeatability and people who are able to go after more difficult and involved problems rather than just low-hanging fruit, which is what I see all my new-R00 colleagues being forced to do. In order to replace the current overreliance on post-doc labor with research scientists, there need to be more funding mechanisms that are specific to this role.

Suggestions for better post-docs and more research scientists:

Replace the emphasis on 'training' with 'independence'. Move a large chunk of the postdoctoral 'training' funding (F and T) to be in the transitional K categories and create a new long-term category specifically for NON-tenure-track research scientists that tenure-track faculty are NOT allowed to apply for. Open up all of these funding mechanisms to anyone with a PhD, no post-doctoral experience required. Funding should be based on the merit of the candidate, quality of the proposal and likelihood of success. Training potential should account for only a small proportion of the K scores and *no* proportion of the non-tenure track research scores. 'Collaborators', but not 'mentors' should be required to fill experience gaps. This will encourage high quality PhDs to stay in academia without needing to be at the personal or intellectual mercy of a gatekeeper PI under the guise of unneeded mentorship.

Update what incentives are rewarded with funding. First or last authorship should not be the only names in the game; diverse, highly specialized and collaborative roles should also be highly rewarded. The PI should not automatically get senior authorship. Also, find ways to extend time limits on training awards if the PI or even scientific journals can verify that a.) a very difficult, high-impact problem was taken on or b.) extra effort was taken to verify repeatability.

Proven or promising external resources or approaches

1) STOP putting so much focus on mentoring and training. We are adults, we have had plenty of training and mentoring and this continued emphasis on training and mentoring actually exacerbates the unequal power dynamic between the post-doc and the PI. Put more focus on autonomy and independence. Post-docs should be able to apply for smaller funding opportunities that give them options—like exploring careers outside academia or switching to a new lab or topic of study.
2) Post-docs and staff-scientists need to have the right to be treated like adults, not being punished for expressing their feelings and beliefs or asserting their own personal boundaries. We need more autonomy to be self-funded, independent of a particular lab and not at the mercy of a particular lab head. The NIH or an unbiased industry partner needs to have in-place groups or mediators who have the power to influence labs, journals or even withhold funding which can help in a truly confidential, independent and unbiased way with conflict resolution and support of the personal and academic rights of research scientists, post-docs and graduate students to work in conditions that are fair, respectful and give proper credit to everyone involved in projects. Due to their own monetary interests, the Universities are not capable of providing such services.

Response 1680

Perspectives on the postdoc roles and responsibilities

It is unfortunate that doing a postdoc has become almost a prerequisite for competing successfully for an academic faculty job. The challenges of the position—uncertain length and outcome—make it such that persons who do postdoctoral fellowships are more likely to have the privilege and resources to "wait out" or "push through" until they land a job. That said, I valued the training and mentoring I got during my postdoc and ultimately it has made me a stronger researcher.

Fundamental issues and challenges

Most postdoc fellowship salaries are tied to the NIH minimums; however, there should be a cost-of-living adjustment, like the existing federal government (GS) scale. The low salaries of postdocs greatly contribute to the lack of diversity in the postdoc workforce and who is competitive for subsequent faculty jobs. The NIH should also support parental leave policies during postdoc training, including allowing grant funding to pause during parental leave.

These major issues of salary and parental leave are not unique to postdocs; they are serious issues for faculty and staff in academic environments too. However, the postdoc is by design a tenuous, temporary, and uncertain career stage, which makes these issues all the more important to improving the pipeline from PhD to postdoc to faculty.

With respect to increasing postdoc salaries, however, I recognize that increasing postdoc salaries will then often result in R-level grants being asked to cover larger portions of salary in order to hire competitive postdocs. After increasing postdoc salaries, it is imperative that the total size of R-level NIH grant budgets also be raised so that this change does not affect the "purchasing power" of the grant. It is my understanding that the grant budgets have not changed in >20 years; therefore, purchasing power of each grant has diminished substantially since then.

Existing NIH policies, programs, or resources

I have 2 suggestions:

1. Expand the number of career development awards that support postdocs (e.g., K99/R00 awards) to transition to a faculty position.
2. Expand the number of career-development awards that do not require substantial training components.

Successful K99/R00 grants seem to need to propose substantial training in new areas; however, there are fewer options for those who need

Response 1681

Perspectives on the postdoc roles and responsibilities

To me, the academic postdoc provides an opportunity to learn a new area of your field while expanding on the skills and knowledge gained from a doctoral program. I see it as an opportunity to continue to develop as a researcher and move toward independence in achieving funding, publishing papers, and leading research. However, I have also heard from people outside academia that it is viewed as "another training position," or a "continuation of your PhD," and coupled with the relatively low pay, it can seem like a position that does not adequately value the skills and knowledge of a PhD. When comparing a short-term postdoc to a more stable position in industry or government, postdoc positions do not often seem like a logical choice.

Fundamental issues and challenges

One salient issue for me specifically is difficulty balancing personal circumstances with the demands of a postdoc. When thinking about relocating to another university for a postdoc, as is encouraged by the NIH to be competitive for funding, it is difficult to justify moving, having my partner leave their job, and find suitable housing in a new location given the current NIH postdoc salaries. The short-term, insecure nature

of a postdoc makes it difficult to consider moving during a time when we are considering having children. If there was more of a guaranteed pathway from a postdoctoral training position to a faculty position, it might make more sense to relocate, but the stress and burden of moving a family as it currently stands does not make sense. Ultimately, I have been deterred from a career in biomedical science because of a perceived inflexibility in the written policies or unwritten expectations for how a doctoral student should transition to a postdoc and then to a faculty position.

Existing NIH policies, programs, or resources

I would urge the NIH to reconsider their policies and expectations around pursuing postdoctoral training at different institutions from the candidate's doctoral institution. According to the National Science Foundation, the median age of a female PhD recipient in 2016 was 32 (https://www.nsf.gov/statistics/2018/nsf18304/report/age-at-doctorate-award-what-are-the-overall-trends-and-characteristics/characteristics-of-doctorate-recipients-sex.cfm), an age when many women consider having children. If women had the option to seek out postdoctoral training opportunities in different departments or labs at their doctoral institution and still be competitive for NIH funding, this could help address the "leaky pipeline" problem by allowing women and their spouses to have more agency over their geographical location and not have to relocate for a short-term program during a potentially stressful time of personal transition.

While I have reviewed the NIH policies on explaining reduced research productivity due to parental leave in biosketches, I wonder if there might be a better way to account for these issues without necessitating disclosure of deeply personal circumstances that may include infertility, pregnancy loss, or other similar issues. As it stands currently, women are being put in a position of having to explain why we are not equivalent to men. The policies should not make a man's career trajectory the default; rather, they should be modified to better accommodate the needs of a variety of career trajectories that take into account the unpredictability of life as a norm; not something that should be asked for as an accommodation.

Proven or promising external resources or approaches

Funding mechanisms that create a pathway from postdoc to assistant professor at the same location starting at a higher level of pay could incentivize individuals to relocate for such positions. In considering non-academic career options, the factors that stood out as selling points were: opportunities for advancement at the same company, clear policies for paid time off (including parental leave), salary potential, and remote work opportunities that would allow me to remain geographically stable. If some of those factors could be addressed through future postdoctoral funding opportunities, I believe postdoc recruitment and retention would improve.

Response 1682

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

Fundamental issues leading to postdoctoral training are the extension of time to get to the post-doctoral position and funding opportunities after that. First, many graduate programs are looking for individuals with extensive training like post-bac positions or RA positions. This could be around 2-3 years time post-bach degree. Then we have the PhD, if you get in on the first applications cycle another 5-7 years. Then the first post-doc 2-6 years, followed by a potential second post-doc of 2-6 years. This means you are roughly 30 by the time you may have a permeant job and up until this time your are considered a trainee and you are not getting benefits like retirement, childcare, ect. This limits who can do a postdoc. Second, to secure funding, there are grants to help post-docs transition, however, many have age recruitments or time post-PhD. This does not align well with older individuals, individuals who take time for caretaking responsibilities, or individuals who needed to do a second post-doc to stay on and eventually go on the job hunt for a faculty position. Additionally, each of these steps will most likely require moving to a new institution. This is not feasible for everyone. THis puts trainees into debt, especially where most top-end sites are in large cities. Additionally, trainees shouldn't have to justify why the couldn't move. You can be a great scientist, and be location bound. But often, scientists are deducted points in grants for this.

Existing NIH policies, programs, or resources

Response 1683

Perspectives on the postdoc roles and responsibilities

A postdoctoral position is a preparation step toward a career as a principal investigator or staff scientist. It is meant to expand your scientific and/or technical expertise and to develop a niche for your own independent scientific pursuits. In addition, it is a time to develop other PI skills including mentoring, grant writing, and lab management. A postdoc benefits the lab they are in by training and mentoring students and pushing forward lab projects.

Fundamental issues and challenges

Why start a postdoc when you could be making 2-3x the amount of money (+ better benefits) in industry? I've made a choice to stay in the academy because I want to become a PI at an academic institution, but this decision has come with a sacrifice that would not be possible if my partner did not make a decent salary. It is very difficult to follow the academic path without outside financial stability. how does this later impact the socioeconomic diversity of the academic system? Many postdocs are in their late 20's and early 30's—a time when many are trying to buy homes and start families. When push comes to shove, post-docs are humans who need to make enough money to support their lives and families.

Existing NIH policies, programs, or resources

NIH fellowships support some childcare expenses, these should be expanded.

Retirement benefits are generally not offered to graduate students or postdocs, meaning scientist must delay meaningful retirement saving for the first decade of their career. This is problematic.

The K99 award timeline works best for scientists who pursue projects that move quickly (prelim data available, cell-based). Longer projects (discovery, model-system based) are less likely to be completed within the 4 year timeline. More time might allow more diverse projects to get funding, which in turn will better help those scientists get academic positions.

Proven or promising external resources or approaches

No response

Response 1684

Perspectives on the postdoc roles and responsibilities

- An academic postdoc is a trained (but also in training) scientist; an established expert in a given field (that of your doctoral dissertation), but seeking to advance your scientific standing by deepening your scope within your subfield, or by shifting to a complementary subfield.
- You're an autonomous scientist, but still under the 'safety net' of an advisor/PI while you transition from graduate school to being able to support your research line independently.
- It's supposed to be a transient position during which the extra training/experience on top of your doctoral work is supposed to serve as a competitive advantage for your independent research career.

Fundamental issues and challenges

- Salary ranges are highly discrepant with job expectations and modern costs of living. Job expectations have evolved to a faculty-equivalency: expected independent/external salary support and research grants; participation in scholarly activities like peer-review/seminars/professional organizations; etc. However, salary rates are ~ 50% less than average research faculty positions. Annual updates in NIH postdoc salary ranges do not scale with education level nor economic inflation.
- The above HIGHLY influences postdoc recruitment/retention. Ironically, we are trained to be critical, rational thinkers. Yet, the current professional climate makes the pursuit of an scientific career in academic research irrational and unviable career path to support a family and future retirement.

Existing NIH policies, programs, or resources

NRSA fellowships: expand eligibility to doctoral students on track for successful dissertation defense, and expand the year limits under T/F32 funding. I submitted my first F32 application in the final semester of my doctoral program, but the fatal criticisms for my application were related to the fact I had yet to start my postdoc position upon applying. Alternatively, I was fortunate enough to be supported by a T32 fellowship at my postdoc institution. However, this creates a 'catch 22' situation where the time required to establish 'evidence' of a working relationship with my mentor is impeding on my eligibility for an F32. This dichotomy creates multiple negative implications: no incentive to be proactive and apply early; deterrence from T32 opportunities because that 'starts the clock' on your funding window; consequently, this leaves PIs to support postdocs financially in order to 'buy time' as the postdocs develops a competition NRSA application, which is counterintuitive to the 'pathway to independence' expectation of postdocs.

Proven or promising external resources or approaches

No response

Response 1685

Perspectives on the postdoc roles and responsibilities

Postdocs are the backbone of US research, the majority of which are immigrants. The way in which various institutions treat postdocs who are people in their late 20s and early 30s is frankly, horrific. Postdocs are the jack of all trades in the lab, capable of performing experiments, writing papers, writing and aiding with grants, training students, supervising PhDs and presenting research at conferences etc. At the same time we are chasing limited faculty positions, trying to define our own research area and continuing the research PIs have requested. The academic community has consistently belittled the value of postdocs in terms of salary, yet needs them to produce ground breaking data. The math simply doesn't add up. The new generation of postdocs is highly aware of the social injustices that are pervasive throughout academia and they will not stand for it. We know our value, industry jobs will pay us appropriately and recognizes our worth and provide a true HR department. Why am I not legally entitled to vacation? Why can't I afford a family? Why can't I have a pension or a quality of life similar to my peers not in academia? Why am I doing groundbreaking research on the edge of human knowledge but yet being classified as a "trainee"? When will academia and the NIH wake up? Why can we purchase equipment on the scale of $200k but I struggle to afford rent? Your "business" model is failing, and unless immediate change is made, US research will fall behind. The general stalemate between institutions and the NIH for salary increases is embarrassing and shameful. While you ponder and discuss the postdoc "crisis" has erupted. Truly this is an awakening not a crisis.

Fundamental issues and challenges

The reference of postdocs as trainees is misleading. Postdocs represent are some of the most highly educated and well trained individuals in the world, many of whom hit the ground running, making immediate impact in new labs post PhD. By characterizing them as trainees this often leaves them open to failing employment standards as they gain further "experience" reminiscent of lowly paid internships. PIs are able to have highly trained labour to produce data for grants, write papers and even edit grants whilst paying them a tupence. This role is in fact more similar to an assistant managerial role. For reference, assistant managers in fast food chains (e.g. Panda Express) on average make more than Postdocs (~$79,360/year in e.g. NYC, Glassdoor). Why are people who are pursuing fundamental questions about human life and existence not paid appropriately? We're not asking to be millionaires, but we should be

treated fairly and able to afford an acceptable quality of life. Inflation has essentially removed this for most postdocs in larger cities. Most PIs no longer perform experiments in the lab and likely haven't in years. If the current situation doesn't change you will essentially be left with a pool of middle management, incapable of actually performing the research.

Existing NIH policies, programs, or resources

Increase the salary. Reprimand PIs who don't respect postdocs (or others for that matter). Give us realistic expectations, legal entitlements, pension options, a good quality of life.

Proven or promising external resources or approaches

I implore you to look at the online discussions about this e.g., Twitter, the various nature papers describing the situation, the unionizing, the protests, the PIs who can't hire people, the money for grants not able to find people. I applaud the NIH for collecting this data with this survey and for having metrics, but if this turns out to be simply lip service you can likely say goodbye to the fantastic research the US has been known for. You don't really need this survey to be honest. The ivory tower is crumbling due to neglect of the key item which built and sustained it, postdocs. The entire system needs to be rebuilt and now is the time. Please take advantage of this moment and make real impacts on the backbone of research.

Response 1686

Perspectives on the postdoc roles and responsibilities

I've been directly told by junior faculty members and fellow postdocs that you don't do a postdoc unless you have to. You do it to gain the skills necessary to obtain your desired career. My goal is to be a staff scientist at NIH, thus I am a postdoctoral research fellow at NIH. Other than being a tenured faculty member or government employee, you don't have job security as a scientist. I worked in industry before graduate school and saw that they hired for specific projects and would promptly fire when it was completed or the project was canceled. Long-term job security is more important to me than an industry paycheck that may not be consistent, and it isn't reasonable to expect to obtain a faculty position anymore.

Fundamental issues and challenges

Students leave undergrad with tens to hundreds of thousands in student loan debt. On average, they take 2 years off before entering graduate school to be a competitive candidate for a top-tier institution (the degree alone is not enough). The avg time to degree in cell biology is over 6yrs, during which you are making enough to cover living expenses and could potentially support a family, but you must be savvy with money in order to save. People enter the postdoc at age 30, except now accruing interest on loans, making not much more than graduate students, may need/want to support a family, all while never have retirement benefits. The avg postdoc is 7yrs before obtaining a tenure-track faculty position, which are harder to obtain than ever as the number of tenure-track positions have not scaled with those obtaining PhDs, and non-tenure/adjunct positions have increased. Even if you're privileged to make it this far (had little/no student loans nor a family to support, successful graduate and postdoc careers), you are unable to financially plan for your future until your late 30s. Independently of that, native Canadian and European postdocs I know have avoided or partly regretted coming here, or try to leave if they can obtain a position outside of the US. They (somewhat colloquially) say they could be shot, have poor insurance to cover the medical expenses, and realistically have harder times starting families because pregnancy and birth are expensive, they lack social services provided by their home country for childcare, and do not have reasonable maternity leave.

The smartest people I went to graduate school with, the ones you want to be PIs leading independent research groups, went straight to industry because they couldn't afford to continue with the academic track.

Existing NIH policies, programs, or resources

1. Reduce the amount of NIH grant money spent on indirect costs, administration, and do not permit it to be used to pay student tuition. I took 4 classes in 6yrs at an R1 institution and TA'd, and my advisor still had to pay tuition.
2. Postdocs are inherently transient, therefore salary should be heavily increased as opposed to providing retirement benefits. People can then personally save more for retirement or start a family, purchase a home, pay off loans, etc.
3. Postdocs are a more valuable resource than graduate students, and staff scientists (even in academic labs) are even more valuable than postdocs because they are permanent/don't have training periods. Generate more staff scientist slots at NIH and incentivize/establish scientist roles in NIH-funded academic labs. Provide job security for people to remain in academia/government without being faculty members.
4. It is both disheartening and infuriating for postdocs to see the amount of administrative staff that support the intramural labs, and the significant difference in salary and benefits. Postdocs work incredibly hard and deserve to be paid equally.

Proven or promising external resources or approaches

It doesn't matter how "good" the environment is. If you can't afford to be a postdoc, you won't be a postdoc. It's that simple.

Response 1687

Perspectives on the postdoc roles and responsibilities

The postdoc is a time of advanced research training in which the postdoc gains experience that complements their doctoral study. The postdoc should gain more independence in directing their research and thinking of future research plans and funding. My postdoc was the most enjoyable part of my career.

Fundamental issues and challenges

Pay needs to be increased and long-term career opportunities need to be provided. The competitive academic job market discourages graduate students from even trying the academic career path. Graduate students have also been provided more extensive career training events for non-academic careers. A large percentage of our first year graduate students intend to go into consulting or venture capital at the time of matriculation.

The increasing emphasis on DEI and DEI statements in academic job applications, while encouraging to URM aspirants, probably reduces the number of white and Asian males who choose to pursue a career in academics. The net effect on postdoc numbers could be negative.

Existing NIH policies, programs, or resources

The NIH cannot increase the number of faculty positions, and that probably isn't desirable. I think the R50 program should be greatly expanded such that being a long-term research scientist becomes an attractive career option. These grants should offer generous salary ($100-$150K in current dollars) and good benefits and enable the awardee to switch labs. A funding percentage of 33% is a good objective. The awards should be competitive, but also abundant enough such that someone who stays on top of their field and publishes good work is able to have a stable career.

Proven or promising external resources or approaches

The French CNRS system is a good model, though the pay is somewhat low. They do offer stability, but their lifetime employment guarantee is probably a non-starter in the US.

Response 1688

Perspectives on the postdoc roles and responsibilities

It's a job that requires no experience that helps build skills and/or experience until you can land next much more rewarding job.

Fundamental issues and challenges

Pay is extremely low for the responsibilities and educational requirements. The training is nebulous if present at all, and amounts to day to day research equals training despite that grad school and other professional posts are the same in expectations. The experience is not unique in what it offers, but is still often required for both academic and industry research roles. Also not being paid as an employee on a W2 leads to institutional loopholes that are financially damaging to fellows who were competitive enough to secure funding. Not being on W2 changes benefits the postdoc is eligible for.

Existing NIH policies, programs, or resources

More money (like a lot more money). Pay on W2 no matter the funding source.

Proven or promising external resources or approaches

No response

Response 1689

Perspectives on the postdoc roles and responsibilities

For me, the postdoctoral position is an opportunity to continue growing in my scientific career. This provides the chance to explore other fields different from the one studied during the Ph.D. and also it can provide valuable information to see if academia is the right fit.

Fundamental issues and challenges

There are many things to improve. As an international scholar, I had a terrible experience with the department at the university and the international student office. Given that you have to do all your visa paperwork and the university is not investing in you, I felt that I was disposable and not valued by the institution. I wasn't a student but I wasn't also an employee so I had all the responsibilities required of me but none of the benefits the university grants to its students and staff. Now I am fortunate that I am in an institution that values me as a person. Not everywhere but I know that there are labs with ridiculous expectations in terms of the amount of time you have to spend in the lab. Also, the compensation for the work in some places is not reasonable for all the things a postdoc does. Yes, it is a privilege but we are also trained scientists that are providing value to the places where we work. Another issue is that there is often a conflict of interest between the advisor and the postdoc, especially in terms of what research the postdoc can use to start his or her own lab. I have witnessed how a PI was willing to take the work and grant submission from a postdoc to use it in her own research grant taking this postdoc's opportunity to start her independent career.

Existing NIH policies, programs, or resources

I'm not familiar with the policies and resources but I think that the policies are as effective as the way or method used to enforce them. I have seen many initiatives fall flat because one thing is what it is written in grants and applications and another one is what actually ends up happening.

Proven or promising external resources or approaches

I think PIs have an oversized influence on grad students and postdocs in their future careers. There are many conflicts of interest between the advisor and mentee, there should be a way to prevent this from happening. However, this approach takes time and PIs would not be willing to add one more task to the list. Another thing I have noticed is that in the totality of my scientific career, I was never taught many of the skills needed to be a PI. Being a PI is similar to being the CEO of a company minus the support and structure to build that CEO to a leadership position. This training has to start from the beginning of our training in our Ph.D. programs and it has to feel like a benefit and not a burdensome task.

Response 1690

Perspectives on the postdoc roles and responsibilities

I have trained almost 40 post-docs. The role of the mentor is to provide guidance (scientifically and personally) and to insure that the post-doc is getting the appropriate training in all aspects of science (rigor, ethics, etc.) while in training.

Fundamental issues and challenges

We are having a terribly time finding postdocs who are well trained US citizens or permanent residents. Most of these people are now going into biotech companies since they pay 2-3 times more.

A second problem is that the postdocs we are attracting are not as well-trained as in past years. This reflects a "dumbing down" of curriculum and expectations at all levels (including graduate school).

Existing NIH policies, programs, or resources

ALLOW NON-US CITIZENS TO BE ELIGIBLE FOR TRAINING PROGRAMS!

Proven or promising external resources or approaches

All of the above.

Response 1691

Perspectives on the postdoc roles and responsibilities

For me, the postdoctoral position represents an opportunity to deepen my academic and technical knowledge as a scientist by engaging in additional training, networking, and leading a scientific project. It also respresents an opportunity to gain insight into the administrative side of science (grant application, how to run a lab, how to set a minimal infrastructure for sustainable independent research) by aiding PIs on all of these duties. Finally, I also think a postdoc is an opportunity to refine transferable skills that can be useful in industry and the public sector (leadership, communication, decision-making, team work).

Fundamental issues and challenges

The fact that postdoc salaries are not being adjusted to inflation rates and local cost of living is making this stage of academic career unsustainable. I live with my spouse (who is not allowed to work on the US), and we barely make it to the end of the month. As an international recruit, I also had to lend money to move to the US, so I started my postdoc already around 8.000 dollars in debt. My wife has had to receive medical care a couple of times, and bills are so high that we need to cut down on groceries to pay for healthcare services. Because of this financial hardship, our relationship has been tense. It is no surprise that those with an offer from the industry do not think twice to leave their postdocs. Starting salaries in industry start 25.000 dollars above entry postdoc salaries, but sometimes can even double it.

Another issue is the poor prospect of career advancement. Most postdocs know it is virtually impossible to get a permanent position in the same institution where they work, so if you don't want to uproot yourself (yet again), you are forced to remain in financial hardship. For those who want to apply for professorships, the only option is to hope for an offer elsewhere in the US or the rest of the world. For those whose partners are unemployed this might be a possibility, but for those whose spouses are lucky to find a well-paid job, it is virtually impossible to follow this track. Some married postdocs will have to choose between a fair salary and their families.

Existing NIH policies, programs, or resources

I feel like a good portion of the postdoctoral community in the US is made up by international recruits, which means we are not familiarized with the NIH at all. In my particular case, this might be the first time I have read about the programs and resources (although I have been a postdoc for only 4 months). I would like to know more about these programs, but I have no knowledge or information of workshops and events by the NIH to introduce new recruits to such policies, programs and resources.

Proven or promising external resources or approaches

Postdoctoral researchers in European institutions have competitive salaries that match the reality of cost of living in local cities, on top of yearly holiday bonuses, high-quality healthcare programs and special benefits for married and with-children recruits. I think this is an effective way to make postdoctoral researchers feel valued, and would certainly favor retention and job satisfaction. I know it is not all about salaries and benefits, and that there are many other fronts for improvement. However, it is difficult to even think of more effective mentoring and training policies when the reality is that highly-trained and educated individuals in the US sometimes earn less and have fewer job benefits than any other non-qualified employee in the job in the market. If the pay scale for postdocs is not updated yearly to match inflation and cost of living, and if there are no benefits that make posdoctoral researchers feel valued,

more of us will likely migrate to industry once we have the chance because this seems to be the only way for us to have a fulfilled life as professionals. We love to do science, but we also want to live a decent and happy life.

Response 1692

Perspectives on the postdoc roles and responsibilities

The postdoctoral position is intended to flesh out the skills and training I will need to be successful as an independent investigator. This entails development of professional networks, grant writing skills, laboratory skills, and mentorship from more senior researchers. I see it as the last year training is inherently built in and accountability for that training is held by both the postdoctoral fellow and mentor, but the goal is that the postdoc is able to move into an independent role as a next step.

Fundamental issues and challenges

Postdocs are significantly underpaid and therefore, undervalued. Often postdocs have been in training for over a decade and in places where research assistants are unionized to make a living wage, are being paid similarly, if not the same to research assistants. The low pay influences decisions about where a postdoc can live, which directly influence their quality of life. Pay also limits who can even feasibly consider taking a postdoc—individuals without familial or partner financial support cannot live on a postdoc wage alone in many large cities. On top of low pay, many postdocs require relocation, incurring moving costs that can easily be upwards of $10,000 for securing a apartment alone in a major city.

Existing NIH policies, programs, or resources

Raising the postdoc minimum salary to reflect a living wage, with cost of living adjustments based on location.

Proven or promising external resources or approaches

No response

Response 1693

Perspectives on the postdoc roles and responsibilities

Postdocs SHOULD be short-to-medium range positions which provide opportunity for additional training to individuals who are pursuing careers in science. This training can include things like research specific techniques or skills (wet lab, assaying, data analyses, etc), mentoring, grant writing, manuscript publication, teaching, and more. In addition, they should provide space for these individuals to build a foundational body of work to showcase their expertise and success in a given area to future employers.

Fundamental issues and challenges

Postdocs are the most abused, underappreciated, and discarded group of humans in science. The pay is terrible, especially when you consider all of the jobs that become available with a PhD. Many of the PIs who hire postdocs do not view it as a training opportunity, but rather a cheap source of expert labor to run their labs, train their other members, churn out papers, and do the majority of work without any tangible compensation. They abuse a power dynamic wherein their letters of rec and publications are the difference makers in a postdocs future career. International postdocs are even more frequently abused, being subject to immigration and work laws that tie their livelihoods even more pervasively to their PIs. This doesn't even cover the disgusting gender dynamics that force female postdocs who are frequently forced to choose between careers and families, the rampant racism against scientists of color, and other social dynamics that have kept old white men in positions of power well past ages of retirement. I honestly cannot think of a worse working structure for a group of highly educated individuals anywhere else in the world. It's laughable that the NIH even needs this survey to understand why postdocs are leaving and implies a certain willful ignorance if the PIs collecting this data are so shocked that a group of people are finally tired of being used and discarded, leaving positions with horrible mental health. As a former postdoc at the NIH who left because of a horrible PI, I tried to affect change by using the on-campus resources for support. But the position of a PI is so unassailable, that nothing changed. I hope PIs learn to live without postdocs, because they don't deserve them.

Existing NIH policies, programs, or resources

1. Pay more so that people can have a real living wage
2. Bolster the reporting and accountability resources so that PIs don't have such an insurmountable advantage when it comes to reporting problematic behavior

Proven or promising external resources or approaches

It's interesting that you ask for "proven" or "promising" external resources or approaches because it provides an easy way to dismiss ideas when you finally aggregate this feedback since it may not meet that high threshold. Especially because in science, things are almost never "proven".

Response 1694

Perspectives on the postdoc roles and responsibilities

The postdoc should be a time to explore and expand your scientific interests, picking up new skills while developing your research program. It's also a time to create collaborations, finish up remaining projects from graduate school, and define future career goals/trajectory.

Fundamental issues and challenges

I had a "prestigious" federal postdoc fellowship that paid the NIH minimum salary (54k in 2021). This fellowship didn't include funds for a raise or any benefits (healthcare, retirement, moving, etc) since you could either use the budget for research or benefits since the provided amount was also too low to do both. I did successfully win another grant to help offset research costs for a field season, but still do not have funds to extract or sequence my samples, resulting in a research bottleneck. I also paid out of thousands of dollars out of pocket to move to and from my postdoc institution, resulting in a large amount of credit card debt since both my graduate stipend and postdoc stipend barely covered the cost of living, even in low cost of living cities. As a women of color, I had to move to another city and establish new community in a department that largely didn't know (or care, frankly) that I had even joined it, and found the lack of racial and gender equity in the postdoc population jarring. Further, because I was independently funded, my PI was much more absent in helping me develop a feasible project using the new skills I was developing. While I would have loved to stay in research longer, when the opportunity for a permanent job at a livable wage emerged, I needed to take it for the sake of my financial and future familial wellbeing.

Existing NIH policies, programs, or resources

The NIH needs to significantly raise stipends at both the graduate student and postdoctoral levels, as well as provide supplemental funds for research and benefits. They should also hold universities more accountable for the treatment of postdoc trainees, as it's a very vulnerable early career position to be in if you're funded by your PI and/or an international student. At the minimum, having NIH staff to consult on taxes would be incredibly helpful, as NSF would never speak to us about how and what to characterize ourselves as.

Proven or promising external resources or approaches

The National Postdoctoral Association may have some resources, but I relied most heavily on the WoCinEEB slack community since it provided opportunities for peer mentoring.

Response 1695

Perspectives on the postdoc roles and responsibilities

Postdocs are purported to be a training position in which a recent graduate can learn new skills, apply for grants, and grow into their own as a full fledged researcher. What it has come to actually mean is a stagnating position you take when you can't get anything, yet are expected to work as a fully functional scientist with little to no actual training provided. For this "honor", you are paid basically nothing when industry pays twice as much and provides better benefits and better work life balance.

Fundamental issues and challenges

The pay is too low. In order for an academic post-doc to be competitive with jobs on the market today, they must offer pay equivalent to a Scientist 1-2 in industry, i.e. $75,000-125,000 depending on location. Yearly cost of living increases that keep up with inflation need to be provided. Better health insurance and 401k offerings must be provided. Wages must be taxed using a normal W2 so that people do not need to file quarterly taxes. There needs to be a clear path to promotion and the creation and highlighting of staff scientist positions commensurate with experience and equivalent industry level created.

Existing NIH policies, programs, or resources

The NIH pay rate and job benefits. People do not take post-docs because they get better jobs in industry. It is that simple.

Proven or promising external resources or approaches

Provide more money

Response 1696

Perspectives on the postdoc roles and responsibilities

I see the position as a way to become familiar with more aspects of my research interests, be it learning new practical skills for conducting experiments, or being introduced to new perspectives from which to view approach research questions. I also see it as an opportunity to explore my interests outside of my core expertise. Responsibilities should include, but not be limited to assisting with ongoing projects in the host lab, exploring novel directions for the lab which align with personal interests, and mentoring graduate students. In this context, authoring papers is expected, but I feel the focus on this aspect of science is detrimental to creativity and mental health of everyone involved. Therefore, I believe it is important to maintain a balance between producing quality research and fostering a healthy work environment.

Fundamental issues and challenges

Salary is by far the biggest issue inhibiting recruitment, retention and overall quality of life, amongst my peers, there is not a single individual who would disagree with that. It is also incredibly obvious from online discourse (i.e. on Twitter). Many studies point towards the inadequacy of a postdoc salary to maintain a reasonable standard of living, especially in areas with higher cost of living (e.g. New York, Bay area, etc.). Let us not even compare against many peers of postdoctoral researchers (calling them trainees is nothing short of degrading) who work in industry and receive significantly higher salary. I can accept that a for-profit industrial company is able to pay their employees more than an academic institution can pay a postdoc, but there is a limit to how little you can pay highly skilled workers who can see that they would be paid much more elsewhere.

In addition, many work environments in academia are far from healthy, with lab heads who have disproportionate power over ones career and oftentimes zero guardrails from the institution to ensure they do not actively exploit the researchers working in their labs. The concept of work-life-balance is nigh non-existent in some labs where working late hours and on weekends is expected, which only rubs salt into an already painful wound of being woefully underpaid.

Response 1697

Perspectives on the postdoc roles and responsibilities

Postdoctoral position, to me, means independently investigating scientific topics of interest with the added benefit of an experienced mentor.

Fundamental issues and challenges

The primary challenge, time and again, is salary. PostDoc's are highly trained individuals whom have completed demanding PhD programs yet PostDoc's on average are paid ~55K$. This pay is absolutely insulting and it feels as though it is surrounded by an attitude that boils down to, "it was like this for me so it is fine that it remains this way." In most major cities this amount of pay is hovering around, or below, the poverty line. Individuals who are PostDocing are also thinking about other important things such as starting a family, trying to buy property, or in general, surviving life in an expensive city without falling into deep depression. The salary is pathetic and reflects a lack of value for postdocs that is absolutley inappropriate. The job itself is general very time consuming and you become responsible for more than just yourself as you find yourself mentoring other students, graduate students, or technicians while barely being able to scrape enough money together to afford rent, especially if god forbid you decide at an age of 30+ it may be time to love alone like an adult. This is a major, glaring issue with the academic post-doc system that if not addressed in a significant way will lead to a significant downturn in academic seeking professionals.

Existing NIH policies, programs, or resources

Provide more insight into how to run a lab independently, how to juggle grant writing with research, and how to tailor grants to increase your chances of success when applying. In addition to this, there should be programs to show postdocs and other academics what it would mean to transition to industry and what that world looks like. The overall ecosystem varies greatly based on which lab you are a part of but there should also be systems in place to be able to safely negotiate salaries both with your advisor and with the NIH as most institutions follow NIH guidelines for PostDoc pay. Lastly, there should be direct communication from the NIH to postdocs about their salaries and how they are able to live, in general, you would be surprised at how many postdocs are severely depressed because they cannot have flexible income.

Proven or promising external resources or approaches

No response

Response 1698

Perspectives on the postdoc roles and responsibilities

A postdoctoral position is an opportunity for scholars to push themselves beyond the topics and techniques that they pursued in graduate education. For those interested in staying in academia, it's commonly regarded as the last non-independent phase of career training before establishing one's own research program. For these individuals, this position should involve getting prepared for/going on the job market, completing research projects, growing a network of mentors and peers, and gaining skills in mentorship and communication.

Fundamental issues and challenges

Postdocs are the forgotten group. There is rarely infrastructure for their personal and professional development like there is for graduate/faculty cohorts, and they are severely underpaid for their level of education and specialized training. International postdocs face further challenges like retaining their visas and living abroad without support networks. Many departments do not provide opportunities for postdocs to give departmental seminars/colloquia, and there are fewer funding opportunities and awards available compared to career stages that come before and after the postdoc period. Further, universities frequently punish postdocs that bring in their own external funding by cutting staff benefits such as health insurance, retirement funds, pay raises, etc.

Existing NIH policies, programs, or resources

NIH grants and fellowships for postdocs should entail stipulations that preclude universities from classifying recipients as anything other than how other postdocs are employed and compensated. This would help keep postdocs from being financially punished for their awards. Further, the extramural NIH minimum pay scale is routinely used by universities to justify under compensation, even when PIs want to increase postdoc salaries. The NIH should raise these minimums and standardize intramural/extramural salaries, especially in light of inflation and the exorbitant costs of living in many metropolitan locations across the US.

Proven or promising external resources or approaches

https://www.nature.com/nature-index/news-blog/how-institutions-can-better-support-their-postdoc-fellows

URM postdocs are disproportionately impacted by challenges in the pursuit of an academic career. Provide additional funding for networking opportunities, workshops, and resources that will enable them to succeed in academic spaces. Provide funding for PIs to undergo mentorship training specific to retaining and supporting their vulnerable postdocs.

Response 1699

Perspectives on the postdoc roles and responsibilities

Primary role should be individual training, and developing additional skills to be a successful independent scientist, regardless of the next career decision. The postdoctoral position means to me that this is a temporary position to benefit further training, be that a new system or field. The postdoctoral position should be independent, yet an advanced position in the lab and as such should be regarded as a competitive position with pay and benefits that reflect that. Similar to a senior scientist.

Fundamental issues and challenges

The main challenge for recruitment is the pay scale. Postdoctoral trainees often have between 5-10 if not more years of relevant laboratory experience. The current pay scale is very difficult to live off of with most city's cost of living. Further, there are no competitive incentives to take this career trajectory. Personally, I spent several thousand dollars just in moving and relocation costs, that I was told would not be covered. This bankrupted me prior to beginning this job. Further, this is a temporary position, and as such is unstable. It's difficult to invest in one's future if you don't know what jobs will be available in 3-5 years. The academic job market is not built to retain postdocs. It's difficult to invest and succeed with minimal pay, minimal PTO, limited healthcare, unaffordable parking, etc.; thus, the quality of life is poor compared with other jobs available. We are highly skilled individuals, and a position of a postdoctoral trainee does not offer enough value.

Existing NIH policies, programs, or resources

NIH postdoctoral payscale needs to be modified and increased to be competitive with industry positions, and to be a livable wage (ideally beyond a livable wage).

Proven or promising external resources or approaches

Training for research careers beyond academia. NIH has a good set of webinars and resources in place already. But people are not going to be recruited or retained as a postdoc under the illusion that there is an academic faculty position available to them.

Response 1700

Perspectives on the postdoc roles and responsibilities

The postdoctoral position is typically viewed as training for subsequently assuming an independent research role in a variety of settings. While this is often accomplished by a good postdoc position, there are multiple competing demands placed upon the postdoctoral fellow's time and energy. The postdoc is typically responsible for doing the majority of the manual labor for a key portion of their mentor's research agenda. They are frequently tasked with orientation and training of other trainees, from junior postdocs all the way down to visiting high school students. Ultimately, the postdoc needs to publish high-impact research in order to be successful. If this does not occur after the first postdoc, further postdoc positions may be required before a transition to independence is possible, if at all.

Fundamental issues and challenges

The most important fundamental issue facing postdoctoral fellows is the difficulty obtaining independent research funding at the transition point to independence. The impact of this is even more severe than the obviously dire paylines would suggest, due to the deterrent effect: even those having success in their postdocs may be intimidated by a payline at the 89th percentile, and doubt their likelihood of success. Rising student loan debt and costs of living are not met by existing postdoc salaries, and while the LRP is

helpful, it too is competitive. Moreover, graduate school and postdoctoral fellowships are very stressful, taking a toll on physical and mental health, and often exacting a toll on fellows' personal lives and relationships. To be faced with equivalent or greater stressors at the transition to independence often seems to be too great a burden to shoulder. Faced with uncertain prospects in academia, and often having been personally witness to the travails of junior faculty at their institutions, it is not surprising that less perilous roles in industry or other private sector employers have significant appeal.

It should also be noted that the scarce funding climate creates perverse incentives regarding the choice of research agendas and areas of investigation. While many individuals go into science intending to break new ground on a pioneering area of investigation, they are quickly taught by participation in the grants process that this is no way to get funding. Any truly innovative idea is sure to be identified by at least one reviewer as "unlikely to succeed". While some disillusionment is inevitable with increasing familiarity with any endeavor, this has attained to high levels in science, and is discouraging to postdocs.

Existing NIH policies, programs, or resources

The scarce funding climate drives trainees to seek roles with the most prominent investigator they can find, in order to better their own likelihood of impactful publication and subsequent funding. Junior investigators therefore suffer from a dearth of good postdoc applicants. This dynamic also functions at the level of the institution, with smaller institutions struggling to recruit trainees, and larger institutions finding themselves awash in highly qualified individuals. For the latter, this feeds a perception of abundance even as the wider scientific labor market is in disarray. Postdocs themselves are aware of this dynamic, and may feel that they cannot be successful if they do not land a job at a "top" institution. NIH policies should be amended to avoid overconcentration of grant funding at institutions that already enjoy hundreds of millions of dollars of annual funding, and encourage new centers of expertise at other research-oriented institutions. NIH should cast a skeptical eye on the multiple concurrent R01s often held by senior investigators, as these same investigators often have access to funding through other avenues by virtue of their prominence, such as industry, private benefactors, university foundations, and intellectual property.

Proven or promising external resources or approaches

There is an increasing perception of the scientific workforce as a pyramid scheme: the actual work is mostly done by trainees, only a fraction of which will ultimately attain the role they are ostensibly training for. Accordingly, there should be increasing appreciation and funding for the technical scientific workforce, including an expansion of career pathway technical roles and staff scientists. The NIH must ensure that fellow stipends keep pace with costs of living and student loan burdens. And most importantly, there has to be a light at the end of the tunnel: if the only reward for years of relentless labor is a tenuous junior faculty role with poor likelihood of funding and success, then there will continue to be a withdrawal from this line of training, to the detriment of the scientific endeavor generally.

Response 1701

Perspectives on the postdoc roles and responsibilities

I decided to enter a postdoctoral research position in a top-ranked medical research institution following graduate school. I saw this position as an opportunity to learn additional research skills, improve my grant writing, and most importantly begin working on several projects I began developing while finishing graduate school. Initially I believed a postdoctoral position was the next natural step in becoming an independent research scientist. I was excited to begin working on independent projects after receiving great feedback from graduate mentors and my current postdoc mentor. I am fortunate to have a wonderful mentor (PI) and a supportive research environment. If I continue within my current position I am confident I will make notable contributions within my field of expertise. Additionally, I have been told for many years that a postdoc position may afford me the opportunity to eventually become an independent scientist. As part of my training I have also begun mentoring undergraduate students. However, after working as a postdoc for ~1 year I am developing serious reservations about eventual career progression. I have noted that many postdocs at my institution have been at the postdoc level for 7+ years without securing a tenure track position despite having excellent publication and grant funding records. Although I am fortunate to have found an excellent mentor at a top-ranked institution and my research is progressing, I will not be able to continue as a postdoc for the number of years it takes to find a full-time academic position.

Fundamental issues and challenges

I believe the NIH has failed to make postdoctoral positions competitive and therefore recruitment and retention has suffered. I know a number of doctoral level scientists that obtained significant funding and high-level publications during their time in graduate school. Most have now left academic institutions and obtained industry positions following graduate school, or after a year of postdoctoral training. The primary drivers of this decision is tied to financial and quality of life issues. These issues are why I will not be able to stay in an academic postdoc for much longer. To be within commuting distance of my institution I must live in a high cost-of-living area. Yet, I am paid one-third of what my industry salary would be given my skill-set.The fact that in 2023 the NIH starts T32 postdocs at $55,224 is disgusting. The stipend provided by NIH is simply not livable and is so far from competitive it is disturbing. I, like most graduate students and postdoc, am a hard worker. I understand that there will be some long days. However, to remain competitive in my field I often work 10+ hour days and will do so without complaint. When I break down my salary per-hour I make less now than what I made as a full-time research assistant PRIOR to entering graduate school. Obviously the financial constraints have negatively impacted my quality of life. It is difficult to see other scientists who left for industry positions progress in non-career areas of their life when you are unable to because of your salary (i.e. unable to purchase car, a home, save for retirement, etc.).

Existing NIH policies, programs, or resources

To enhance the postdoctoral and academic research training ecosystem I believe it is imperative for NIH to increase stipends. This will encourage talented scientists to remain in the academic pipeline. Furthermore, it will help scientists from more humble financial backgrounds remain in the academic field. I have begun to notice that several postdoc researchers at my institution who have been able to remain in the academic 'waiting room' while they search for tenure track positions, have a significant other or other family member(s) that provides significant financial support. This is especially true of women I am working with that have small children. My research institution has no onsite or subsidized childcare. Therefore postdoc parents must somehow pay out of pocket for childcare. This is next to impossible in a high cost-of-living area. NIH should work with academic institutions to ensure there are childcare options for their researchers.

Proven or promising external resources or approaches

I believe NIH should better monitor the use of postdoc positions on research grants at academic institutions. Although I am fortunate to have a supportive mentor who is interested in advancing my career, I have seen other PIs at my academic institution treat postdocs like lab techs. For example, while researching postdoc labs in graduate school I noticed that many PI's had long lists of requirements you must have prior to applying for a postdoc position in their lab. I suppose this is to ensure the postdoc could begin working on current projects immediately. Many requirements included newer and difficult techniques (i.e. in vivo miniscope imaging during awake-behaving animal behavior). For this reason I was not able to even apply to several labs that I initially thought would be a good scientific fit given my research interests. I can understand if PI's want a few select working lab skills when hiring a new postdoc but this is still considered a training position. If someone must know all possible techniques before entering a lab what part of the position is training? I believe these PI's should instead be required to hire research scientists using their NIH funding. This would enhance the overall postdoc environment by ensuring that PIs actually provide training and input into a postdocs career, instead of just using them as over-educated and under paid lab technicians.

Response 1702

Perspectives on the postdoc roles and responsibilities

A post-doc typically has two roles, one is to apply the skills (conducting research, publishing etc) learned from their PhD to a new area. The other is to learn additional skills (preparing grants, managing people) that prepares them for an independent research career.

Fundamental issues and challenges

Post-Doc is an inherently unstable position. It is typically an annual contract in which it might be continued or not. This lack of stability means that some people might have to switch positions more frequently at the whim of funding.

Existing NIH policies, programs, or resources

Funding such as the K99/R00 is the only clear path which guarantees that a post-doc will become a faculty member. It ensures that an individual has some monetary investment that encourages departments to invest in a candidate and minimizes the perceived risk of a hire. Even other career awards (K01, K08 etc.) does not guarantee that an institution will offer a tenure-track faculty position and startup package. NIH should offer more K99/R00s. There should also be more opportunities of funding for international post-docs—especially the ones that train in the US for their PhD. And more opportunities for supplements to add a post-doc to a grant and would provide protected time for the post doc to develop their own direction separate from their PI's funding.

Proven or promising external resources or approaches

Frequent evaluation and re-evaluation of programs is important. Examination of the success rates of individuals from programs (k99, F32 etc) helps support the ones that are most important to invest in. They also help to indicate to departments which programs are more likely to generate a successful candidate.

Response 1703

Perspectives on the postdoc roles and responsibilities

A postdoctoral training in academia is a period where we prepare ourselves to become leaders of tomorrow. It is a transition period where our potentials grow exponentially and where we start to observe the significance of our role in our society and environment. It is a period where we make important decisions for our own personal and professional life.

Fundamental issues and challenges

The fundamental issues are numerous. The biggest challenge is poor fundings/low salary. NIH minimal bracket should be increased to pay well the postdocs they deserve. Many institutions just follow NIH's minimal salary wage and treat postdocs at a level way below administrative staff. The administrative staff (with Bachelor's degrees) make more salary than postdocs. At academic cancer centers, postdocs are treated inferior to clinicians (residents/fellows), so as the salary is different. The salary should be well enough for postdocs to have a comfortable living, who have dedicated their life to many years of school to make a difference in the society. The salary should be enough that postdocs need not worry what food they can afford, what they cannot afford, whether they can have babies, whether they can afford to buy a car etc.

Existing NIH policies, programs, or resources

The current system seems like the graduate schools are producing PhDs for industries, the retention rate in academia upon graduation is low. Should increase overall fundings, salary, etc

Proven or promising external resources or approaches

improving postdoctoral recruitment, training, working environment, mentoring, job satisfaction—these should all be improved.

Response 1704

Perspectives on the postdoc roles and responsibilities

Postdocs are supposed to be a time to be trained in a new skill set and potentially transition into an academic position if desired.

Fundamental issues and challenges

Postdocs typically start having families and want to buy a house around this time of life, but aren't paid enough to do that. Publishing in reputable journals is so difficult. It takes an immense amount of time and data and that process in itself can take years, leading postdocs to burn out. With a CNS paper, you are mostly doomed if you want to enter academia.

Existing NIH policies, programs, or resources

Postdocs should not be penalized if they are postdocs longer than 4-5 years. There should not be time limits on when you can apply for career transition grants. If you are trying to publish in a high quality journal, it often takes more than 5 years to do that. We need more resources, not less. Also, we need underrepresented-specific fellowships. It is not an even playing field so URMs need more help in boosting their chances for success. Also, grants proposals should be blinded. Given what we know about implicit bias, it is ridiculous that there is no effort to blind reviewers.

Proven or promising external resources or approaches

No response

Response 1705

Perspectives on the postdoc roles and responsibilities

Complete freedom to perform reproducible and exciting biomedical science. Allow for training in new technology, further the ability to write and present scientific data in a rigorous manner.
Independent of the needs of administrative tasks (or very limited) as to allow for the highest level of creativity.
Increase confidence in all aspects of science (as well as a person) to one can be successful in the next career.

Fundamental issues and challenges

salary—many PhD students feel the need to make quickly a higher salary often to pay down student loan debt.

They also see the long hours and struggle of academia in their advisors.

Existing NIH policies, programs, or resources

NIH needs to start to fund R01s and R35 at levels that are requested and allow to pay for salaries that postdocs need to feel confident to succeed. Any NIH R01 is cut by 20+% automatically reducing the salaries that can be paid. The module needs to be $50k and not $25k as it was in 1998!

NIGMS R35 need to be much larger and not require 50% commitment, which basically requires 50% of the funds of an NIGMS grant being spend on the faculty salary and not allowing for high quality postdoc and graduate student salaries. The NIH needs to stop supporting the universities but rather the faculty that perform the training of the future biomedical workforce in the US.

Proven or promising external resources or approaches

Provide large enough NIH grant that allow for $75-90k postdoc salaries; make the size of NIH grants large enough to allow for postdocs to attend meetings and to allow to pay for supplies and facilities. This will dramatically increase training and job satisfaction and provide plenty of mentoring opportunity.

Response 1706

Perspectives on the postdoc roles and responsibilities

This role has changed over the years. It is my opinion that a postdoctoral fellowship position is a time for a talented scientist to hone their skills to a state-of-the-art level, absorb knowledge and wisdom from their mentors, and learn how to be productive, impactful, and do so in an efficient manner. Self-aware during this career stage then enables the individual to chose a life of science that best suits their scientific skills and career goals whether they be in an academic, industrial, a government lab, and/or in some other area of science.

Fundamental issues and challenges

Career paths in Academics alone, as the only choice, have long past and funding agencies have to let this idea go. Secondly, limiting funding to only Green Card holders and U.S. citizens is short cited and severely limits finding the scientists who are most true to the above roles. Thirdly, career development beyond postdoctoral positions should be something that scientists are trained to do from an early stage in their career versus planning to "land and keep a job" for life. Until this is recognized, unrealistic outcomes are

quickly recognized by the younger scientists, which turns them away from science, which is something they may regret, particularly if they become trained and "miss out" on years of opportunity based a decision they made, which was based on unrealistic outcomes for a career.

Existing NIH policies, programs, or resources

1) Drop the U.S. citizenship/green card rule and choose candidates based on their abilities to do science and communicate to U.S. citizens.
2) Reward postdoctoral programs that do not "limit their success metrics" to having trainees go into academic science.
3) Track the careers of postdoctoral fellows, so outcomes and success can be monitored with real data.
4) Incorporate these "data collection exercises" into database entry methods, which would be part of NIH funding expectations on NIH progress reports.

Proven or promising external resources or approaches

Expand significantly the funding of training programs, so that >50% of the training grants are awarded, not based on anything else but their ability to recruit and train postdoctoral fellows with a simple set of criteria, per program, such that the trainees were funded by NIH-funded grants, and organized to learn, do, and present/train others to do NIH funded research. Have such training programs scale with the number of NIH funded investigators (not NIH funded grants). This would allow for better mentor to postdoctoral ratios and eliminate "large labs of competing postdocs within a single lab".

Response 1707

Perspectives on the postdoc roles and responsibilities

I view the postdoc as a temporary training position preparing a biomedical scientist for an independent position.

Fundamental issues and challenges

The fact that postdocs on NIH fellowships cannot be university employees creates all kinds of problems for them (some lose access to benefits, retirement accounts, no W2 means that they have trouble applying for credit, etc.)

The NIH recommended stipends are difficult to live off of in many parts of the country (not just the biotech hubs on the east and west coast).

Wildly varying quality of mentoring results in some postdocs having great experiences while others have a really horrible time and sometimes drop out of biomedical sciences as a result.

Existing NIH policies, programs, or resources

More individual fellowship options, less reliance on T32s

Proven or promising external resources or approaches

CIMER mentor and mentee training resources, mechanism to share best practices

Response 1708

Perspectives on the postdoc roles and responsibilities

Turning the wheel of science with highly trained hands and minds.

Fundamental issues and challenges

Extremely low pay, bar none. My non-PhD scientist wife makes twice as much as I do in an entry level biotech/pharma position. How do you think that makes me, and others working as academic post-docs, feel about their value as highly skilled scientists???

Existing NIH policies, programs, or resources

Post-doc pay.

Proven or promising external resources or approaches

Increased post-doc pay.

Response 1709

Perspectives on the postdoc roles and responsibilities

A postdoctoral position should be primarily working on your own independent projects and developing collaborations or relationships with other professionals. Postdocs should be responsibility for only their own independent and/or mentored projects. A postdoc should have the time, freedom, and flexibility to only work on projects that interest them and/or further their own line of research and careers.

Fundamental issues and challenges

Postdocs SHOULD NOT be research coordinators for a PI. Postdocs should not only work on their advisors projects. Postdocs SHOULD NOT have only one advisor/mentor. Postdocs need higher pay and full benefits equivalent to a full time research coordinator or professor. Adjust pay for cost of living/localities (as federal gov does). Increase professional support (money for training, workshops) and research (supplies, etc.).

Existing NIH policies, programs, or resources

Cost of living and/or locality salary increase. Research support funding increase. Ensure projects do not have a single mentor. Ensure postdoc projects are independent from advisors. Program officers should speak directly with postdocs.

Proven or promising external resources or approaches

Look at federal postdocs (veterans affairs) and how that compares to non-federal.

Response 1710

Perspectives on the postdoc roles and responsibilities

The postdoc position is a training position, but one with advanced knowledge and skills required. It is a stepping stone to other positions so so the postdocs own goals cannot be forgotten in order to advance those of their mentor.

Fundamental issues and challenges

Salary is a huge one. With my experience and in my area, I could go take an industry job and make double what I do now. This would also come with at least the potential of improved work-life balance. When I am worried about money and thinking about maybe having to do Doordash or Instacart on the side to make ends meet, that is not sustainable.

Existing NIH policies, programs, or resources

Enforcement of NIH policy compliance. Postdocs at my institution report that even though they are on a T32 they are not getting the yearly raise. They are also denied use of the childcare stipend because the university says it is not equitable for some to get that and some to not.

Proven or promising external resources or approaches

No response

Response 1711

Perspectives on the postdoc roles and responsibilities

I view the postdoctoral position as the first real job in academia. In this position, the post doc has support from a department or senior faculty member as they develop their program of research, starting pilot trials, working on manuscripts, preparing grant submissions, and rounding out their training experiences to become an independent researcher.

I view the postdoctoral position as the entry point into the career I've been training to pursue for over the past 12 years. For me the post-doc is an opportunity to round out training experiences that may have not been addressed during my graduate work, and to become an independent clinical researcher, preparing to secure independent grant funding.

Fundamental issues and challenges

First and foremost is the salary! I'm frequently questioning my current commitment and likelihood of continuing on the academic research trajectory on a postdoctoral salary. I have friends and colleagues who have the exact same training and qualifications that I have who are earning 3x my current income. It's tough to continue down this career path knowing that I can make more and receive more benefits and support pursuing a career outside of academic research. As a single parent living in a major city with a high cost of living, it is difficult to feel motivated to continue on in academic research knowing that my qualifications and skills set is more valued elsewhere.

Existing NIH policies, programs, or resources

An other challenge is the post-doc to K to R pathway. There are several barriers on this pathway that contribute to making this a sustainable pathway, including developing a mentorship team, publishing manuscripts with the team to submit a competitive career development award,

Proven or promising external resources or approaches

a proven and promising approach to improving postdoctoral recruitment and job satisfaction, especially in the context of global inflation and cost of living, would be to increase post doctoral salary to be in line with the cost of living.

Response 1712

Perspectives on the postdoc roles and responsibilities

The role of a postdoc is to address specific gaps in their own knowledge, qualifications, and experience towards application for academic jobs. This includes research, mentoring, networking, publishing, and presenting at conferences, as well as teaching and service as appropriate. The role of a postdoc is also to support the research of their mentor or team even when it does not help to address specific gaps in their own knowledge, qualifications, and experience. This may include all of the same activities listed, but typically involves skills or topics not pertinent to the postdoc, or excessive time spent relative to training value.

Fundamental issues and challenges

The short of it: It costs me $100,000 a year in lost compensation to be a postdoc.

The long of it: I get paid less on an hourly basis than the student researchers around me even before accounting for their tuition and health insurance both being paid. I can obtain health insurance through work, but I have to pay for it. I am not eligible to make retirement contributions through my employment. My institution is currently working on getting paid maternity leave for post-docs. Within a month of applying for jobs, I could be earning well over twice what I currently make with additional benefits (like a 401K, paid health insurance, and paid m/paternity leave). The only reason for me to be a postdoc under such circumstances is because I genuinely like my job more than the additional money I could be making in industry.

Note: I get paid in accordance with the NIH NRSA stipend levels, and my skills are highly quantitative.

Existing NIH policies, programs, or resources

The NIH has a lot of influence over my compensation. Tell me you value me by making it standard practice to compensate me. Everything else is well and truly besides the point when we're talking about $100,000 a year more I could be making elsewhere in wages and benefits.

Proven or promising external resources or approaches

No comment

Response 1713

Perspectives on the postdoc roles and responsibilities

Continue to develop scientific skills by independently carrying out a project (or projects) investigating a certain area of research. Mentor graduate students and undergraduate students, if applicable. Apply for grants (K awards, F awards, etc).

Fundamental issues and challenges

Low pay and low benefits (ex: health, childcare, etc). Not enough protections from predatory PIs. Long/multiple postdocs in part due to increased competitiveness amongst few open faculty spots. Longstanding issues within academia that are well-known but have not been sufficiently addressed (publishing & securing funding being the main two).

Existing NIH policies, programs, or resources

Increased protections for postdocs, similar to graduate students. Increased benefits for postdocs, similar to PIs.

Proven or promising external resources or approaches

No response

Response 1714

Perspectives on the postdoc roles and responsibilities

Development of project ideas and execution, Learning grant writing, presenting at meetings. Getting regular feedback from supervisors.

Fundamental issues and challenges

Poor salary makes it hard for individuals who with young Children to continue in academia due to increasing rent and childcare. A lot of the labs require long hours of work leading to exhaustion. Again individuals with young children faces challenges to continue in such environment.

Existing NIH policies, programs, or resources

Adjusting salary based on geographic location and cost of living.

Proven or promising external resources or approaches

Policy should be placed to practice work life balance. Restricting hours of work per week or day will be helpful. A lot of places only offer 14 or 15 days of sick leave plus vacation which could be increased

Response 1715

Perspectives on the postdoc roles and responsibilities

Academic postdoctoral positions should provide career counseling, networking, and skills development through immersive experiential training at job sites. The pay should be commensurate with the skills level.

Fundamental issues and challenges

Pay is too low. Both private industry and Federal employers can offer six figure salary training experiences. That is coupled with exposure to relevant skills training and networking.

There is also pressure to complete the academic post doc before you "age out of the system" at 5 years post degree. Combine this with the lack of stability and difficulty finding jobs after post-doctoral training, it becomes a very stressful trap.

Why would anyone do an academic postdoc? It is a dead end job that pays poorly.

Existing NIH policies, programs, or resources

Incentivize PIs or labs that create more permanent mid-level and non-PI laboratory pathways. If possible, a minimum number of senior scientist positions should be required in academic labs that apply for NIH grants.

NIH should not award grants to PIs who are known for exploiting foreign scientists. If everyone in the lab is on a J-1 visa, this is a major red flag. NIH should consider conducting site visits to labs like this to talk to trainees separately from the PI. Sanctions should be implemented to discourage this behavior from PIs.

Create incentives for PIs who actually support the career growth and development of their postdoctoral trainees. The five year time limit on postdoctoral training penalizes fellows, not PIs. There is extreme pressure to publish or get out. If your experiments fail, you aren't given many options to recover. Trainees sometimes publish sloppy research in low end journals to survive. This doesn't benefit anyone.

Proven or promising external resources or approaches

Partner with private industry and scientific Federal Agencies to openly advertise and support those career pathways. Pretending like we will get academic research positions is insulting.

Response 1716

Perspectives on the postdoc roles and responsibilities

Primary roles include running a project, writing and publishing manuscripts, obtaining funding, teaching and mentoring new lab members, and representing the lab at meetings. Depending on the lab, other roles often include troubleshooting equipment, lab maintenance, and monitoring student progress.

Fundamental issues and challenges

1. Salary levels are extremely low compared to what equally qualified individuals earn in industry jobs (usually industry is double the post-doc salary, other options can be more than triple).
2. Benefits (health insurance, retirement, dental, etc) are low
3. Many important grants (e.g. F32 and K99) are only available for short windows of time after receiving a PhD. This makes it difficult to plan time for pregnancy, child care, potential illness, taking care of aging family, or any other life events.

The combination of these three means that post-docs, who are usually in their 30's, feel unable to realistically plan for paying off student debt, having children, and owning a home, unless they have financial support from their parents or a partner with a better paying job. Therefore, being an academic post-doc is a luxury that many qualified and hard-working scientists cannot afford.

Existing NIH policies, programs, or resources

1. Increase budget for salaries
2. Improve inflation adjustments for minimum salary requirements
3. Adjust time-windows for important grants

Proven or promising external resources or approaches

No response

Response 1717

Perspectives on the postdoc roles and responsibilities

I don't really see a good layout of the roles **and responsibilities** of the postdoc. In general, I should run and design my own experiments, producing results and data at a faster pace than any graduate student. On top of that, I should be writing grants, mentoring other students and younger post-docs, and any other task that the PI doesn't have time for. I see postdocs as lab managers as well. We do everything to keep the lab running below writing R01s.

Fundamental issues and challenges

We are expected to get grants and fund ourselves but when we get these grants our benefits including retirement are reduced. I think a huge issue is pay, we came out of our PhDs making almost nothing (my PhD paid me $15000 a year), so I incurred a lot of interest on my student loan debt. I know academia cannot match industry in terms of pay that is why the benefits are so important but when we get NIH-funded fellowships we lose most of those benefits. The new childcare costs is nice but it only really covers a month or two of childcare costs, it feels like the NIH is out of touch with what it takes to live above poverty. Being a woman and a postdoc I really have to concern if I can stay in science because of the costs. I also have to try to pay back my student loans, which got more interest as I couldn't pay them by making next to nothing during my Ph.D. Also, the length of time as a postdoc before you can move into a research scientist position (if that's your next choice step) should be clarified. I'm told 5 years I have to stay at my postdoc before I can move into any type of position but at other universities, they only need 2 years. If pay needs to stay low there has to be other benefits and perks that keep postdocs, including more help with students loans, childcare, and retirement.

Existing NIH policies, programs, or resources

The loan repayment program should not just be for medical doctors. There should be options for basic scientist in every field. I had a postdoc friend who was able to get help with students loans in 2015 by being a basic neuroscientist, however, since then there has been nothing for those types of postdocs.

Proven or promising external resources or approaches

No response

Response 1718

Perspectives on the postdoc roles and responsibilities

I am currently a senior graduate student and am actively pursuing a postdoc position. To me, a postdoc is an opportunity to develop my own scientific identity and gain additional skills essential to ultimately setting up my own lab.

Fundamental issues and challenges

There are two primary issues. First, is the significant pay reduction relative to most entry-level positions in academia. Second, is the process of acquiring postdoc positions. It is informal and thus dependent on students directly approaching a potential advisor. A related consequence of this is that you need to be aware of the person you are contacting. If, instead, there was some kind of central location where positions were posted students and potential advisors would both have access to a wider range of possibilities.

Existing NIH policies, programs, or resources

Funding. Simply put, the NIH minimum has not kept up with the increase in inflation and cost of living. The other is the availability of retirement funds. Often, if you have an NIH-funded postdoc, as opposed to being funded directly by an institution, there are no retirement benefits. This disadvantages trainees in the future.

Proven or promising external resources or approaches

No response

Response 1719

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

I did a Fogarty fellowship in Peru, interrupted surgical training and brought my one year. Would be more attractive to trainees if compensated adequately to not require going into debt (for travel, storage of possessions, etc.) in order to do the fellowship. While I would favor it not compensating well enough for

the compensation to be an incentive, right now the compensation limits accessibility for people without additional financial means or with children.

Existing NIH policies, programs, or resources

I would favor more experiences which require < 0.4 protected FTE for research—may improve the accessibility of the resources for clinician investigators who will have solid foundation in ensuring work is relevant to the field of interest.

Proven or promising external resources or approaches

No response

Response 1720

Perspectives on the postdoc roles and responsibilities

The postdoctoral training period is an important phase of academic training. It represents a phase in which individuals can hone their knowledge in specialized areas, gain new skills, and have protected time to develop their own research questions.

Fundamental issues and challenges

Cost of living has increased throughout the US over the past few years and postdoc salaries are not competitive. On top of this, R01 budgets have not increased nor kept up with inflation--making it very challenging for PIs to cover postdoc salaries. Increases in both of these would help with recruitment and retention. Secondly, for postdocs with career training awards (NRSA for example), universities/NIH are placing additional burdens on postdocs by not providing W2 tax forms (and instead giving 1099s). This should be addressed and changed.

Existing NIH policies, programs, or resources

The NIH policy of limiting to 4 training years for postdocs to apply for K99 awards is too restrictive. I appreciate the motivation (to help postdocs move efficiently into academic positions) but with the competitive funding environment this means that postdocs need to have a fully developed plan in their 2nd/3rd year. In particular, for postdocs who work with Nonhuman primates (NHPs), experimental timelines are much more extended. By year 3, it is not reasonable to expect postdocs working with NHPs to have a competitive academic record that is comparable to those working with model systems in which experimental timelines are much shorter (e.g. fruit flies, mice, c.elegans). Furthermore, the budget for the K99 phase is too small to cover most NHP work. This is cutting off opportunities for NIH to preserve the academic workforce working with NHPs, and will have far-reaching impacts in the next few decades.

Proven or promising external resources or approaches

No response

Response 1721

Perspectives on the postdoc roles and responsibilities

Great opportunity to grow as a scientist, acquire important skills, and develop as an academic.

Fundamental issues and challenges

The postdoctoral pay scale (NIH) is abysmal. I live paycheck to paycheck and am unable to save for retirement as a 30 year old. The only thing keeping me in academic research is my passion for research, but I see many of my colleagues do important research in industry and get paid double what I currently earn through my K award.

Existing NIH policies, programs, or resources

Improve postdoctoral pay.

Proven or promising external resources or approaches

No response

Response 1722

Perspectives on the postdoc roles and responsibilities

From the perspective of a graduate student, an academic postdoctoral position is a transitory one where you are able to fill in the gaps of your training before moving on to a faculty position. It seems like a highly competitive and rushed position as the number of postdocs far exceeds the number of available faculty positions within academia. As someone who intends to go into industry, an academic postdoc seems like a waste of time or a hindrance to me jumping into a full-time industry career.

Fundamental issues and challenges

I think the main thing preventing the recruitment and retention of postdoctoral trainees is the low stipend in comparison to the amount of work and expertise required for the position. Postdocs often take on the more risky projects within the lab and then may struggle to publish or get their name out to line up a faculty position.

Existing NIH policies, programs, or resources

I think training or exposure to other career options is crucial for both postdocs and for graduate students. Not every graduate student can pursue a postdoc and not every postdoc can pursue a faculty position. The expectation of everyone to stay in industry is unrealistic and causes lots of stress and competition. Funding should also be increased to reflect the position.

Proven or promising external resources or approaches

No response

Response 1723

Perspectives on the postdoc roles and responsibilities

I view the postdoctoral position as similar to the old guild system.a graduate student is an ‘apprentice scientist’ while a postdoc is a ‘journeyman scientist’. In other words, they have more independence than a graduate student, but still work under the auspices of a ‘master scientist’. In that vein, a postdoc is still a training position-which is often used as an excuse to not pay postdocs very well.

Fundamental issues and challenges

Low pay is one of the most prominent challenges; after 8-10 years of post-secondary education, postdocs still barely make enough money to support themselves. This drives many potential postdoc candidates to other career paths (such as industry or consulting).

Existing NIH policies, programs, or resources

NIH sets the pay rate for most postdocs based on what they are willing to fund in grants. If the NIH decides that postdocs are worth more, then they could increase the amount allowed to fund postdoctoral salaries.

Proven or promising external resources or approaches

No response

Response 1724

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

Lack of pay raises. Low starting salary for a demanding position. No guarantees on health insurance. Lack of any other benefits. No retirement savings. Competitiveness of job market—hard to compete for academic faculty positions without top papers that are hard to come by without dedicating 10+ hours per day including weekends. No compensation packages. No daycare assistance.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1725

Perspectives on the postdoc roles and responsibilities

In my view, a postdoc is an experienced and independent scientist acquiring additional training, usually in developing their own ideas, mentorship, and leading others, as these skills are necessary for many of the future careers a postdoc might undertake. While a graduate student should learn to be a discerning and careful scientist in a supportive and limited framework, a postdoc should have the freedom to explore and develop their own direction, mentor and train less experienced scientists, and learn about management in general. They should be more productive and require less help and guidance than a graduate student, often forming the core of the lab in both scientific progress and mentorship. However, they should still be mentored and supported by their PI who should take a special interest in helping them succeed in reaching their next goal, whether it be a faculty position or otherwise, rather than assuming that a postdoc will just figure out what they need to do without any real support or advice. If postdocs are just going to be expected to be completely independent and succeed without support, they might as well already be faculty/a research scientist/etc.

Fundamental issues and challenges

The main obstacle I see for postdocs is the salary. As we continue to extend the training periods before scientist get to "real" jobs (ie faculty, research scientist, etc) and as we expect postdocs to produce more , it is unreasonable to continue to pay them as if they are in a transient position that is fully a training role. Though postdocs should be receiving training and support, they are also already highly trained and productive, often being the major sources of scientific output of labs, and should be compensated as such. Jobs in industry requiring similar training (and providing similar or sometimes even more extensive mentorship and support) to that required of a postdoc often pay close to twice as much, highlighting how underpaid postdocs are for their work. More importantly, it is financially prohibitive for many people to become postdocs, especially if they have dependents or other financial responsibilities, which ultimately prevents those who lack the privilege to be able to "afford a postdoc" from pursuing this position. Another obstacle is the way that postdoc training is viewed by many PIs. In my experience, PIs often just see postdocs as workers who should drive the lab's research forward, get what they need to move to their next step, and then figure out how to do what they need to do in their next step on the job (probably because often this is what PIs themselves had to do). However, with applications for these next steps becoming more competitive and doing a postdoc becoming more necessary to succeed in these roles, it might be time to rethink this view and use the postdoc not only to get people to the next step but also train them in the skills they need to succeed once in that next step.

Existing NIH policies, programs, or resources

To address the major obstacle of pay, increasing the NIH postdoc salary would help immensely. Additionally, allowing for adjustment of salary based on a region's cost of living would also be very helpful. Though equal pay across the country is nice in theory because it allows for institutions in less favorable locations to have the benefit of better pay to cost of living ratios, this unfortunately unfairly pushes those with more difficult financial situations to have less choice while those with more privilege can "afford" to choose an institution/lab in whatever location they would like. To address the issue of updating postdoc training, the NIH could update or add to the trainings that NIH-supported PIs are required to take, adding information on the types of mentorship and support that PIs should provide. In my view, though postdocs are already highly trained and scientifically independent, there are other types of training and support that PIs should be providing, including actively teaching management and mentorship skills, providing career advice and facilitating networking connections in the relevant fields, and generally preparing postdocs for their next step.

Proven or promising external resources or approaches

Response 1726

Perspectives on the postdoc roles and responsibilities

Build and diversify your research portfolio through increasing number of publications
Grow your collaborative research network
Learn to write competitive grant applications
Get experience writing grants

Fundamental issues and challenges

Student loan debt

Financial concerns

Existing NIH policies, programs, or resources

Increase the success rate of F and K awards (i.e., more funding for trainees)

Increase the research funds for F and K awards (i.e., funds are too low to become independent)

Proven or promising external resources or approaches

I am very happy with my postdoc training and my choice to pursue an academic career.

Response 1727

Perspectives on the postdoc roles and responsibilities

I believe the roles **and responsibilities** of academic postdocs are to support their PI or PI's research team for a portion of their time, but a majority of the postdoc's time should be devoted to developing themselves professionally. For example, a majority of my time as a postdoc was focused on developing and publishing manuscripts, which was important when going on the job market. Most postdoc timelines are approximately 2 years and the first year is the time that should be leveraged the most for writing considering that most job cycles open up in the fall, which would be the beginning of most postdoc's year 2. Additionally, my time as a postdoc helped me develop my research agenda and network without the commitment of coursework and administrative meetings.

Fundamental issues and challenges

I think there are a few issues **and challenges** that may influence the perspective of "postdoc life" and the benefits that may come from being a postdoc.

1. Salary and compensation. Postdoc may have moved from their graduate institution to a new position. I don't recall receiving a moving allowance and my salary made living in close proximity to my postdoc location hard.
2. Isolation. In my case, I was the only postdoc in my area and felt a bit isolated at times between graduate students and faculty. I felt like I didn't have others to share my experiences with and ask for advice on how to cope with certain things.
3. Pilot funding opportunities. Depending on the institution, most times postdocs are now eligible for the same pilot funding as graduate students and/or faculty. This is an institutional barrier, I feel, and more institutions should make pilot funding available to visiting postdoctoral trainees.

Existing NIH policies, programs, or resources

If a postdoc is funded via an NIH grant, their salary should be increased. Additionally, possibly pilot funds can be allocated so postdocs can implement a pilot study.

Proven or promising external resources or approaches

Grant workshops, statistically training workshops, postdoc associations at institutions where postdocs across departments can get to know each other and share resources, mentoring for postdoc that may report that their mentor is not providing adequate mentoring.

Response 1728

Perspectives on the postdoc roles and responsibilities

Postdocs are vital for contributing to the scientific enterprise. They help labs by bringing their expertise and different perspectives and they gain from the labs they go to—often by learning a new system, and getting exposed to different approaches, and getting additional skills (oral communication, writing, teaching/mentoring). In the best case scenario, they become collaborators and colleagues during their time in a lab and have the opportunity to develop independence. Some postdocs learn a critical skill set that enables them to get a certain type of job they want.

Fundamental issues and challenges

Several issues came up recently that affected retention: too little pay and the NIH payback rule for the individual fellowships. Some postdocs are single parents. They need affordable on site childcare and parking, both of which are lacking at my institution. The current supplement for childcare is totally inadequate. Many talented students are opting not to do postdocs at all. To some degree I think this is due to the market—they can immediately get high paying jobs.

Existing NIH policies, programs, or resources

Get rid of the payback agreement, raise both the fellowship amounts and grants for PIs supporting non-US postdocs who cannot get individual federal support. Make the fellowships minigrants with more research support to encourage postdocs to do truely independent work (look at USDA's approach). Stop being so conservative about the projects supported.

Proven or promising external resources or approaches

Develop a mechanism for rapid turnaround for supporting postdocs who might need some encouragement to go for an academic postdoc. Be more flexible about what the job entails (some people might want a part time postdoc if they have other family concerns). Place less emphasis on moving institutions—some postdocs need to be in a specific location. Pressure institutions to provide on site affordable childcare, support young parents (I had to convert my microscopy room into a make shift lactation room), free parking.

Response 1729

Perspectives on the postdoc roles and responsibilities

The current expectations for a postdoc are that you are in training for a faculty position and so are expected to act as a mentor to other lab members, manage multiple research projects, apply for grants and write manuscripts, while also still continuing in a research role for your own project. The current recruitment crisis has made balancing all the demands of a postdoc position even more difficult, as we are still expected to mentor and provide support for others in the lab but the ratio becomes skewed, and it comes at the detriment of our own work. I view it as a highly underpaid internship as a PI.

Fundamental issues and challenges

It is hard to justify from a career advancement, financial, and benefits perspective to take on a postdoc where you make half of what is possible in industry straight after completing your PhD, without retirement benefits and childcare benefits afforded to faculty and other research staff, while also maintaining the expectations of performing at a level equivalent to those same academic roles.

As a 2020 PhD graduate, I would have never chosen a postdoc as my path but industry wasn't hiring due to the pandemic, so academia has acted as a safety net in that way, but I have friends of the same age who have less education and make equivalent or higher salaries, plus benefits, so there are many days when it is difficult to justify the time and effort I put into my degree. The love of science does not outweigh the lifetime loss in earnings and other benefits.

Existing NIH policies, programs, or resources

The NIH minimum salary is a helpful policy when advocating for increased pay, but it is not competitive with industry. If salaries cannot be increased, there needs to be additional effort on the part of institutions to provide additional benefit support at no cost to postdocs, since they are not being compensated at a level equivalent to their qualifications.

Proven or promising external resources or approaches

The National Postdoc Association has assembled resources and information on benefits comparisons across institutions. There are enormous discrepancies across institutions, and there needs to be improved accountability in supporting those who are the backbone of productivity in academic labs.

Response 1730

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

Funding. After graduate school many researchers are in debt and have been making essentially minimum wage for the past 4-6 years. The decision to take a postdoc position over an industry position comes with a significant pay cut. Many people are not in the position to be able to take that cut. Increase funding for postdocs and there may be an easier time recruiting and retaining them.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1731

Perspectives on the postdoc roles and responsibilities

When I entered gradate school in 2012, I wasn't sure if I would go on to do a postdoc. It seemed that doing a postdoc was necessary to attain an academic professorship, something I didn't plan on pursuing. There are several reasons for this—in the US, I have been told many times that to pursue a postdoc or academic position in the same university/state as my graduate work is career suicide. I went on to do a postdoc in the same state anyway because I value my local family, community, and neighborhoods more than chasing a career position I probably can't attain anyway. In addition, the lack of work-life balance I have viewed in my academic advisors is not something that is appealing to me. While my work and career is important to me, I have other responsibilities to family and interests of my own that I want to pursue. A postdoc, while not really necessary to me, allowed me extra time to figure out what direction I wanted to go outside academia and to hone some relevant skills.

Fundamental issues and challenges

I spent 5.5 years getting my PhD, during which I had no family support and lived near the poverty line, struggling at times to pay for groceries and other basic necessities. While my peers have been saving for retirement and purchasing houses, I am in my 30s with little savings. On a postdoc salary (starting for me at $48,000 starting out of grad school), it is impossible to catch up. While I wouldn't trade my graduate school accomplishments for anything, it is hard to see the worth of a postdoc when I plan to go into a non-academic job. Luckily, I do not have any dependents, but I cannot imagine the stress of caring for children on such a low salary.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

Get rid of the postdoc job category entirely; we are fully trained scientists and should be paid a decent wage with decent benefits. At my university, I am not even considered a staff member and am not eligible for basic, tax-advantaged retirement accounts. Scientists with PhDs should be able to attain staff scientist roles with full staff/faculty retirement benefits and a livable wage. Academic PhD scientists need respect and decent compensation for our labor just like everyone else. This should not be that hard to figure out.

Response 1732

Perspectives on the postdoc roles and responsibilities

Postdoctoral training should be relatively short and intended as a transition role to get jobs as a group leader in industry or academia. It should not require the same amount of work and time as a PhD, which is how many postdoc roles now are.

Fundamental issues and challenges

If increasing diversity in the academic and scientific workforce is a priority (which it absolutely should be), then postdoctoral training must be well compensated and not stretch for many years. Otherwise, the academic pipeline will continue to select for privileged individuals

Existing NIH policies, programs, or resources

INCREASE THE MODULAR R01 BUDGET CAP NOW!

Proven or promising external resources or approaches

No response

Response 1733

Perspectives on the postdoc roles and responsibilities

I spent 10 years in various postdoc positions, eventually finding a niche that would ultimately lead to a coveted non-tenure track research faculty position. My first postdoc, I learned to write grants. My second, I learned to be innovative. My third, I learned what it is to be brave and have vision. My roles and responsibility widely varied across these positions, but each afforded me a skill set that is now unique and marketable. I have no regrets, but I wouldn't recommend this trajectory to a recent Ph.D. graduate. My journey in science is an adventure.but not a 'career' in the traditional sense. I've come to terms with this.

Fundamental issues and challenges

There were roughly three types of postdocs I encountered over a decade.and this is a broad generalization:

1. Those who had families and/or unique financial obligations;
2. Those who were either married to a higher income earner or from wealthy families; and
3. Those who were flying solo and had more leverage to make individual decisions about their trajectories. I was in the third category. I made a concerted decision to stay in interesting postdoc positions until I landed the type of job I wanted. I did this at the expense of my financial future. I will not be able to retire and I will likely face end of life with relatively few resources. The gravity of this long term decision has not quite set in, but the possibility of ending up in the wrong position and being 'stuck' somehow seems like a worse fate.

Existing NIH policies, programs, or resources

NIH funding hasn't changed in 25 years. This makes hiring Ph.D. level, postdoc-trained academic research scientists or research faculty virtually impossible. It also makes talented postdocs a cheap(er) source of expendable labor. Changing the funding line would create more academic positions for well-trained scientists, encourage more scientists to stay in academia, and make postdoc positions shorter and more fruitful in terms of a career trajectory.

Proven or promising external resources or approaches

There is currently a cultural issue around postdoc labor: these are generally financially vulnerable people (with some exceptions described above) who are often on visas and experiencing even greater vulnerability due to citizenship status. This power differential is a recipe for mistreatment. There needs to be more accountability to these individuals, but this would mean that the NIH would be required to face the realities of its structural and systemic issues which are truly baked in at this point.

Response 1734

Perspectives on the postdoc roles and responsibilities

Postdoctoral position is meant to be a temporary training period to learn a new subset of skills and become more important as a scientist, such that the trainee can be more prepared to lead their own lab.

Fundamental issues and challenges

Postdocs are heavily exploited. Salaries are about a third of what the offers we constantly get recruited out to. Often winning fellowships and grants turns into a decrease in pay. Institutions show very clearly how little they care about postdocs. The expectation has started to become that postdocs will stay for 5-7 years instead of the 2-3 years it should be.

Existing NIH policies, programs, or resources

Increase minimum salaries. Make it so that earning a fellowship helps trainees. Push institutions to at least pretend to care.

Proven or promising external resources or approaches

I know very few people who want to stay as a postdoc. It’s a thankless role.

Response 1735

Perspectives on the postdoc roles and responsibilities

Opportunity to learn new skills/techniques and establish oneself as a leader in their field

Fundamental issues and challenges

Salary and benefits far below comparable early-career industry positions. Difficult to balance of grant-writing responsibilities with research and professional development.

Existing NIH policies, programs, or resources

Move away from 1-year appointments and guarantee positions for the duration of an average postdoctoral appointment. Allow postdocs to be listed as co-investigators on grants to reward time spent on grant writing. Implement area-adjusted salary scales and improve childcare benefits for working parents

Proven or promising external resources or approaches

No response

Response 1736

Perspectives on the postdoc roles and responsibilities

A postdoc position should be to provide a trainee with new training in a different research area and/or in different approaches to answering research questions.

It should not be a position where the trainee is continuing to work in the same area and same way as in their graduate training.

Fundamental issues and challenges

The low funding rates of NIH grants for years has led to a generation of newly minted PhD students running away from traditional postdoc positions in exchange for higher paid industry jobs or alternative science careers. They do not see an attractive future in academic research as a PI.

Existing NIH policies, programs, or resources

Improve K99/R00 paylines. Increase number of NIH Funding opportunities for NRSA fellowships.

Proven or promising external resources or approaches

No response

Response 1737

Perspectives on the postdoc roles and responsibilities

The postdoctoral position lends itself as a means in which to improve the scientific capabilities of the acting postdoc themselves, but also as a means of contributing great science to the overall scientific community.

Fundamental issues and challenges

The reason there are issues with recruitment, retention, and overall quality of life for postdoctoral trainees in academic research is because they are not paid enough. NIH grants have not increased in the amount of money they award, which affects the amount of money that PIs can pay their workers. If you increase the amount of money granted for research grants, the pay for postdoctoral trainees will increase, and then people will actually want to pursue this line of work. Until this happens you will be hit with this postdoc shortage. You have the means to fix this, try implementing it.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1738

Perspectives on the postdoc roles and responsibilities

I pursued a postdoc to prepare me for an Assistant Professor position in academia, government or non-profit institute. I am now applying for the jobs and can say that I have gotten great value out of getting to work on a distinct project from my graduate work so I can now start my lab at the nexus with a set of skills and expertise unique from my mentors. I got to experience a unique mentoring style as my graduate mentor did not collaborate much and I did not get this from my thesis committee. I had finished graduate school conflicted about what to do because I loved doing research, but could not imagine managing a group the way my mentor had. I gave it one last shot with my postdoc and specifically chose this lab because of the good mentor fit and the mentor having a very different style. This will be exceptionally useful in helping me be an inclusive mentor that creates a welcoming lab community for a diversity of trainees with a variety of career goals. The postdoc also allowed me protected time to develop my own research interests from scratch and establish preliminary data. This is also a time to build my network of peers who will be my key collaborators and build relationships with other PIs at my institute and beyond. I wish the postdoc did more to prepare me for managing a lab, essentially a small business. This is an opportunity to shape/train the next generation of the scientific community and induce needed changes, but only publication output is valued or taught.

Fundamental issues and challenges

Pay is far too low to compete with industry and more than 1 year of an academic postdoc is not financially or career beneficial if that postdoc then goes to industry. Academia pays in prestige and that’s insufficient as even associate professors are moving around more and transitioning in and out of industry. The promise of tenure is not valuable because you still need to get grants. Particularly international postdocs are also not provided any visa help and this can mean 3-5 years not seeing their families which is insane and also provides an incredible amount of stress as they try to begin their postdocs. Institutes and universities have very little department specific programming for postdocs and this would be super helpful in making the time more efficient and preparing postdocs better as well as creating a support community that would hugely benefit quality of life. Just providing mentoring committees, TRACKED by the dept and encouraged would help. Providing department community events for postdocs and research events would help. With postdocs arriving at all different times and different life stages and without the benefit of the structured community for grad students (and honestly the value and focus put on them), postdocs get isolated and have to keep reinventing solutions. For the amount of publication and grant productivity that postdocs provide to labs, departments and institutions they are WILDLY undervalued financially and organizationally.

Existing NIH policies, programs, or resources

The NIH standard payscale is quoted across the country and used for minimal postdoc salaries (if they are lucky and they probably need a union to achieve this). This pay is not a livable salary in many cities and a graded scale would help a lot. When postdocs are not recieving any structured training it is unfair and should be illegal to pay them below minimum wage. There needs to be guidelines for how to use the IDP effectively. Just writing goals and having the PI sign off does not provide the incremental feedback on how to break down long term goals and achieve them. Providing PIs with a generalized rubric for what postdocs need to achieve approximately at the end of each year for a variety of career goals would help and enforce equity in this process that often leaves less supported postdocs floundering, experiencing imposter syndrome and giving up and leaving academic research (speaking about people who want to stay). That said, industry should no longer be considered an 'alternative' career. The line between academia and industry is blurring and the emphasis on academia being the 'moral' reserach path is toxic and damaging. It also pushes recent PhD graduates into academic postdocs that do not help them financially and are not the right fit. Fewer postdocs with higher salaries and more focus from departments would be beneficial for all as long as it is accompanied by more graduate training towards industry and other research positions. The role of research scientists needs to be more highly valued financially and then could be emphasized as an additional career path as these experts and incredibly valuable in a labs success long term.

Proven or promising external resources or approaches

Postdoc mentoring committees.

Structured postdoc training for academic careers including how to manage a lab, budget and inclusive mentoring. The UW Future Faculty Fellows attempts some of this.

NIH K99, K22, and DP2 writing courses with faculty available to read specific aims and 'practice' score grants.

IDP with rubric for different skills needed by the time postdocs are applying to jobs. Incredibly important to improve equity with clear expectations.

Structured graduate training for industry careers and research scientist positions so that postdocs can get structured training for academia.

Response 1739

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

The low postdoc salary is probably the largest barrier to recruiting and obtaining talented postdocs. People are instead leaving for industry where they will be paid at least 20K more.It is especially difficult to live on a postdoc salary in the current economy. This also makes it difficult to retain scientists from disadvantaged backgrounds who don't have family wealth to fall back on. Guaranteed paid family leave would also be incredibly helpful for postdocs.

Existing NIH policies, programs, or resources

Postdoc training should include skills necessary to succeed in industry and other non-academic jobs.

Proven or promising external resources or approaches

No response

Response 1740

Perspectives on the postdoc roles and responsibilities

In my experience, a postdoc is a very isolating experience. So far, I have been responsible for every aspect of my work, from conception of a project, planning the experiments, purchasing reagents, executing experiments, analyzing data, making presentations, and then beginning the cycle again. This cycle is endless. There is always another experiment to do, always cells to be taken care of. I'm not sure if

I just don't have what it takes to be a successful postdoc, or if not all postdocs feel as I do. However, it is difficult to maintain motivation to continue a project when many companies are telling me that I don't even need a publication to get a six-figure job with excellent benefits. It is hard to be the one doing 100% of the work on a project and keeping my head up when things inevitably fail.

Fundamental issues and challenges

For me, I am constantly thinking about how much more money, job security, and benefits I could be obtaining by leaving my postdoc and going into an industry position. Many industry positions don't require any publications during a postdoc, making the entire postdoc experience seem unnecessary unless you want to be a PI. I like that I have flexibility and freedom as a postdoc

Existing NIH policies, programs, or resources

I'm not really sure. I'm at the NIEHS and there isn't really a sense of community here. I have been a postdoc for nearly 2 years and don't even know how many people are in our department. Everyone's work is so distinct and schedules often don't overlap. I'm also the only trainee in my lab right now, so I am not getting much interaction with others at all.

Proven or promising external resources or approaches

The main issue that I see right now with the entire postdoc system (not just NIH) is that it simply isn't worth it for the vast majority of PhD holders. Most of us won't be PIs, and if industry will pay us twice as much as a postdoc while offering benefits and room for growth in a company, and if companies don't require a postdoc experience, it simply doesn't make sense for people to want to do a postdoc. In my opinion, it could potentially be more of a shortcoming if someone who doesn't want to be a PI does a long postdoc. In fact, I've been told this verbatim by industry professionals. The hiring individuals in industry don't care about papers, and a candidate with 5 years as a postdoc is going to want a higher starting salary than a fresh PhD. I worry a lot about whether I'm jeopardizing my career by staying in the postdoc position knowing I don't want to be a PI. Sure, you do learn some transferrable skills, but the reality is that most jobs for PhD level scientists don't require a postdoc, and there are not a lot of other incentives for the postdoc experience.

Response 1741

Perspectives on the postdoc roles and responsibilities

The academic postdoctoral position allows a researcher to improve their tool kit and resume while searching for an academic post. If the academic job market were better, meaning more potentially permanent positions were available, there would be no benefit to the postdoctoral position. Unfortunately, searches for tenure-track positions may take years and runaway selection has raised expectations of applicants for those positions. Hiring committees expect to see one or more postdoctoral experiences before hiring someone for what is an entry-level position (assistant professor). After graduate training, many researchers are financially depleted. Taking a brief, often abusive, low-paying position is not great. This is a time when many researchers walk away. This is a tragic loss of resources and talent.

Fundamental issues and challenges

Postdoctoral researchers must see the clear path to scientific independence. A training plan is essential. Postdocs should know their advisor's attitude about the role they will play in the career searches of the postdocs serving in their lab. Unfortunately, advisors are not often truthful about their commitment to seeing their postdocs move from their labs to scientific independence. Postdocs are often left to rely on the grapevine to understand what their professional relationship to their advisor will be, especially if the advisor is early in their career. A statistic similar to the H-index might help.

Existing NIH policies, programs, or resources

Postdoctoral training plans should be required. Postdocs should be informed in clear terms about the likelihood of progressing from their postdoctoral positions to scientific independence. Rigorous statistics on success in different fields should be common knowledge. It is as important as putting the cancer warning on the side of cigarette packs. Institutions that do not regularly place their funded postdocs into independent positions should be deprioritized for future funding for postdoctoral support.

Proven or promising external resources or approaches

Many sources of postdoctoral support expire. The F32, for example, is only available during a brief window. If a postdoctoral fellow completes an F32 fellowship but still hasn't found an independent position, there aren't many options left to them. Expiration dates for postdoctoral funding should be reconsidered. There is a downside to this because some researchers, if allowed, will postdoc forever. NIH should not enable that career path.

Response 1742

Perspectives on the postdoc roles and responsibilities

In my view, the postdoctoral role should be a position that transitions early career scholars into full scholarly independence. The years spent as a postdoc should certainly provide opportunities to continue building their skills as scientists, but also to become knowledge about the variety of career options after their postdoctoral education and the skills they will need to succeed in those roles. Postdoctoral scholars should not be assigned work that is more appropriate for lab techs or students. They should be visible within the academic community as scientists, with opportunities to present at conferences and publish.

Fundamental issues and challenges

As an administrator in a campus international office, I have too many stories of international postdocs being abused by PIs. In less egregious circumstances, I see postdocs running out of time on their visas and unable to secure the green cards they desire because they have not been publishing during their postdoctoral training. Even if outright abuse is not occurring every single day, negligence seems to be the normal state of affairs. Fundamental issues in my view include NIH grantmaking rules, low pay and perverse incentives in our science ecosystem. In the area of recruitment, postdoc pay is low when compared to the level of education these individuals have. I think that the culture of science and the academy more broadly is very compromised today—there is too much focus on getting today's science done and not enough on developing the next generation. The invisibility of postdocs is a huge problem. This invisibility coupled with the extreme stress to secure grants and publish that is ever present in academic departments creates the conditions that are ripe for abuse. I think that addressing these issues requires deep work at the individual faculty and departmental level, coupled with NIH policies that hold PIs and universities to account for mentoring postdocs and creating a positive work environment for everyone. Mandatory mentor training would be a good start, as would evaluating PIs on their mentorship. If NIH and universities insist on calling postdocs trainees, they need to get serious about training. T32 training grants should be made available to international postdocs—this argument about American taxpayer dollars ignores the fact that international graduate students and postdocs also pay U.S. taxes. There is no American science without international contributions. Finally, PIs with a pattern of abuse need their funding revoked.

Existing NIH policies, programs, or resources

The programs coordinated by the National Research Mentoring Network (NRMN) are outstanding and I think should be a mandatory precursor to being a PI on any NIH grant. I greatly appreciate Paula Stephan's work on postdoctoral issues, and was surprised to learn from this paper (https://www.nber.org/system/files/working_papers/w19687/w19687.pdf) that funding for graduate students and postdocs was once separate from research grants. This seems like a wise strategy to consider as it will help with right sizing the academic workforce and ensure that postdocs can leave toxic environments with their funding intact. I also think that IDPs need to be mandatory for postdocs, and that NIH should set a minimum number of hours per month that are dedicated to postdoctoral professional development outside the lab. There should also be an effort to standardize data collection on postdoctoral scholars nationally, with the goal of addressing some of the data limitations that were identified in the 2014 National Academies report. Demonstrating empirically how much the science training system needs to shrink in order for everyone to have viable career options is a must. Universities that receive NIH grants should also be required to offer a full scope of career development programs. Learning how to write grants and mentor is necessary professional development for aspiring faculty, but I would like to see more attention on the NIH side to broadening the frame of career development. For example, NSF funded programs like the National Science Foundation Research Traineeship (NRT) and the Center for the Integration of Research, Teaching and Learning (CIRTL) provide opportunities for graduate students to learn about interdisciplinary and community engaged scholarship, and evidence-based teaching and

learning. These experiences provide highly transferrable communication skills that postdocs can use whether they choose academic or non-academic careers.

Proven or promising external resources or approaches

In general, I think that NIH-funded researchers and people within NIH need to be more conversant with the vast (and growing) scholarship on graduate education and academic careers. Since I work on a campus with only health and human services professional schools, I'm very struck by the degree to which faculty on my campus have no idea about the innovations that have been taking place in graduate education and academic careers through NSF-funded initiatives, like NRT, CIRTL, ADVANCE, etc. There are things that biomedical sciences can learn from those programs, and there's a lot of publications that have come out of those initiatives. Finally, new tools like Project Callisto https://www.projectcallisto.org/ that have been developed to help combat serial sexual harassment and assault outside institutional Title IX processes seem very promising to also combat other forms of abuse. Knowing which PIs to avoid is a function of access to social networks that marginalized people are often excluded from—we need tools to level the playing field so that abusive people pay a price for their behavior.

Response 1743

Perspectives on the postdoc roles and responsibilities

The Postdoc I my opinion is a time period where I am learning, in a new environment, something completely different from my PhD and eventually is a steppingstone to become an independent PI.

Fundamental issues and challenges

- The academic path is now more than ever "high risk and low reward". If joining the "wrong" lab a recovery from this mistake is very difficult.
- Starting a family while being a Postdoc is very difficult
- Strong uncertainties regarding a future as an academic scientist
- Very low salary in comparison to industry
- There is no requirement for institutes to have a career development program

Existing NIH policies, programs, or resources

As a foreigner, I never received an introduction in the NIH ecosystem. I am basically expected to do my project, write grants for scholarships and figure everything out on my own.

Proven or promising external resources or approaches

Unsure

Response 1745

Perspectives on the postdoc roles and responsibilities

An academic postdoc should be leading a high-impact research project as they prepare to apply for tenure-track faculty positions. Postdocs should receive minimal technical training but be mentored extensively on paper-writing, grant-writing, and other managerial skills. PIs should only allow postdocs to work on projects they could take with them when they have independent tenure-track positions.

Fundamental issues and challenges

I believe the 3 biggest challenges are low salary, poor prospects of faculty positions, and lack of control over where you live. PhD graduates are hesitant to take ~2-3x lower salary for ~5 years and then only have a ~20% chance of finding a faculty position that makes sense for both their families and their career trajectory. This large financial & social sacrifice weeds out highly qualified candidates who don't have inherited wealth or have families (even w/o children).

Existing NIH policies, programs, or resources

1. K99/R00 awards should be awarded within the first 2 years of a postdoc. This way postdocs who have poor prospects of obtaining an independent faculty position can leave for higher paying positions at the end of year 2.
2. Create an award similar to the K99/R00 that requires the K99 and R00 funding portions to be used at the same institution. This would minimize the social costs of relocating during the postdoc-->faculty transition and incentivizes institutions to only hire postdocs if they would also be interested in hiring them for faculty positions.
3. Cost of living adjustments for recommended salary. Most academic institutions are in expensive cities and some PIs can use the NIH recommended salary as justification for massively underpaying postdocs. This issue is particularly rampant for PIs who wish to exploit international postdocs who do not have accurate knowledge of a city's cost-of-living prior to signing a contract.

Proven or promising external resources or approaches

Overall, there should be fewer postdocs and those who do elect to serve as postdocs should have higher salaries and more power in the faculty job market. For those who do wish to remain postdocs, this Yale science fellows program seems to have a good approach that balances location stability, development of a research portfolio, and salary https://apply.interfolio.com/108050. I would only consider applying for postdoctoral positions which are structured similarly.

Response 1746

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

The salary does not reflect the cost of living in NYC at all, not even close. No matter how exciting the science is, if the life outside of the lab is full of financial stress, then that's all we remember in the end.

Response 1749

Perspectives on the postdoc roles and responsibilities

The postdoctoral research position is a role were the person does part of PI's project, but is allow to have their own ideas to transition into a PI position. Postdoc should be a training experience.

Fundamental issues and challenges

My experience as postdoc is very bad. PI uses me has technician without allow me to work properly in her RO1 nor my own ideas. Funding is being not properly used for the project.

Existing NIH policies, programs, or resources

Postdocs in RO1 needs to be closer evaluated. I

Proven or promising external resources or approaches

Make a standar survey of postdoctoral training ecosystem in all lab with NIH funding.

Response 1750

Perspectives on the postdoc roles and responsibilities

The role provides the opportunity for protected time to research and publish, alongside the ability to obtain further mentoring and training. These skills are critical to my development as a scientist and the ability to obtain grant funding to support my research.

Fundamental issues and challenges

Challenges include the low pay of postdoctoral trainees, particularly when in high cost of living areas. I was a nurse practitioner earning >$100,000 in the midwest (low cost of living). I accepted a postdoc position in [redacted for anonymity] (high cost of living) with a stipend of ~$54,000—difficult to cover expenses and relocate a family on this salary level. In addition, I considered leaving the position due to the low pay—but then found out that I have to repay my salary if I leave early for a non-research position such as clinical practice. So, next, I considered working as a NP in addition to hours as a postdoc, however, I am limited by NIH rules to 10 hours per week or less outside of the postdoc. Moreover, working in clinical practice during postdoc would eliminate some of the benefits of the position (i.e., protected time for research and publication). Finally, postdocs are not considered faculty, they are temporary, and as such we are viewed as expendable and at times not provided with mentors that are committed to our development (i.e., lack the time). Unfortunately, once you accept and begin a postdoctoral position you can be 'stuck', as I now feel.

Existing NIH policies, programs, or resources

The repayment policy needs removed and pay needs increased.

Proven or promising external resources or approaches

No response

Response 1751

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

No response

Existing NIH policies, programs, or resources

NIH should support more structured transition from postdoc to permanent researcher/scientist position within a university setting. Any person with a total postdoc experience of 3 years should automatically be hired in (a more secure and financially rewarding) scientist position.

Proven or promising external resources or approaches

- Better pay—match the salaries paid by national labs to postdocs
- More opportunities to earn independent funding for postdocs—these opportunities should not require US citizenship or PR
- Automatic switch to a permanent position at the university at the end of total 3 years of postdoc training

Response 1752

Perspectives on the postdoc roles and responsibilities

I view it as another step to get more research experience before starting a full-time job elsewhere.

Fundamental issues and challenges

Money. After 10 years in college, the current NIH pay scale is a bit insulting relative to a job in industry. I know it's more limited due to government spending vs money a company raises selling their products, but it's hard to sacrifice that after so many years earning even less as a PhD student.

Similarly, to still be considered a trainee after 10 years and still not yet be in a final job position is hard, especially as postdocs aren't necessarily being trained as much at this point, other than the training they are doing themselves.

It's also hard to move around a lot--between undergrad, grad school, post-doc, and career after the post-doc, that's a lot of moving, which makes it hard to make roots anywhere. This also isn't necessarily

feasible for those with families or wanting to start families. The cost of moving is also prohibitive as well, especially with the low pay.

As far as training for academic careers, postdoc positions weren't an absolute necessity before like they are now, and certainly not for the duration many are doing now. We're all just too exhausted from grad school to go through another 5 years of a postdoc position before getting a respectable job.

Existing NIH policies, programs, or resources

Higher NIH payscale, especially since many universities/programs base their pay on this.

Proven or promising external resources or approaches

No response

Response 1753

Perspectives on the postdoc roles and responsibilities

As it stands, the US postdoc system is nothing short of discriminating abuse of highly skilled labor. It is facilitated by exploitation of mostly international PhD holders who are kept hostage by a visa system that will negatively affect the US economy, US research community and US patients in the years to come.

Fundamental issues and challenges

Not enough funding is the major problem, closely followed by an unattractive visa system that re-directs highly skilled international PhD holders to other countries.

Existing NIH policies, programs, or resources

NIH grants that fund postdoctoral research have to be adjusted to reflect current cost of living. Local economic environments have to be considered. It is not contemporary to fund a postoc in e.g. Idaho at the same level as a postdoc e.g. in California as these 2 locale have significantly different cost of living requirements.

Proven or promising external resources or approaches

The department of housing and urban development publishes low-income limits for every locale in the USA. Postdoctoral funding should be adjusted to be AT LEAST 80% of the adjusted median income of an area for a 1 person household, i.e. low-income threshold.

You guys know exactly what the problem is: postdocs are not paid nearly enough. You get what you pay for and that goes both ways. Fork out more money are fall behind the global competition.

Response 1754

Perspectives on the postdoc roles and responsibilities

The postdoc is the first step to transition to a independent Faculty/Professor and Scientist. In fact, the training continues, but with more freedom and independence of the supervisor. It's time to transition from most of the bench work done in the PhD to more reading/analyzing/writing work. Also, start mentoring individuals in the lower timeline of academic career.

Fundamental issues and challenges

First of all, the salary. The housing prices and health insurance aren't affordable with the postdoc salary. Second, the absence of a supportive environment with good diversity and inclusion. Third, there are no positions for all the postdocs to have their lab; other career pathways must be evaluated. Fourth, academia as it is now it's not sustainable.

Existing NIH policies, programs, or resources

Include the non-citizen in almost all NIH grants. Most of the science in U.S is made by immigrant postdocs.

Proven or promising external resources or approaches

Lottery for postdocs and students anonymously evaluate their PI, lab, department and research institute.

Response 1755

Perspectives on the postdoc roles and responsibilities

After the PhD, which could be considered the first significant contribution to science one does, the typical next step for a scientist is often a postdoc position. It allows us to fully deploy our acquired abilities to contribute to and carry out research projects. From a career perspective, to me, a postdoc position should be well delimited in time, and allow one to build up CV and reputation to be able to become independent as a scientist.

Fundamental issues and challenges

As much as I enjoy academic work, it does not pay too well. Science and academia is complicated and competitive enough, financial burdens should not be an additional problem we face. If the stipend keeps being meager and does not keep up with inflation, one inevitably considers moving out of academia to find better options that also provide more reasonable work-life balances.

Existing NIH policies, programs, or resources

NIH salary guides should take into account the cost of living of each area, as in certain urban areas, the cost of living is not in line with the current guidelines. I would like to point to the following article: https://www.nature.com/articles/s41587-023-01656-4

Proven or promising external resources or approaches

I think to improve postdoctoral training, recruitment and carer development, NIH should recommend or mandate better incentives to hire and maintain postdocs. At the moment, the main issue is probably the minimum salary, which has not keep up with inflation and is not competitive. Increasing the number of paid holidays, and programs to support mental health will likely be welcomed. From my own experience and many of my colleages, being a postdoc is stressful, and this has a toll, in overall well being, relationships and even health.

Response 1756

Perspectives on the postdoc roles and responsibilities

Developing and sharpen the mindset for a relevant scientific problem

Fundamental issues and challenges

Lack of opportunities after postdoc

Financial low-paid job

Existing NIH policies, programs, or resources

Better opportunities to postdocs

Increase fellowship

Proven or promising external resources or approaches

No response

Response 1757

Perspectives on the postdoc roles and responsibilities

I view the academic postdoctoral position as a temporary training position that should be enriched with career development activities relevant to research. This is distinct from a staff scientist role, which is more permanent, does not have the same degree of career development training opportunities, and should be compensated with a higher salary (than post-docs). After 9 years of post-undergraduate training, a 4-year professional degree program (PharmD) and a 5-year PhD experience, I was willing to do a post-doc, despite the low stipend, only because I knew it would be temporary and that I would gaining experience that would ultimately make me a better academic researcher. In order to ensure, I would be entering a post-doc opportunity that was truly a temporary training experience, during my interviews, I specifically inquired about T32 programs and about the availability of open faculty positions (for after I completed the

fellowship) at each institution. I would not have pursued a post-doc if I believed that it would not be temporary and that I wouldn't learn.

Recommendation: I recommend that the NIH develop a clear list of eligibility requirements that define a post-doc (e.g., evidence that the post-doc is engaged in training opportunities, is attending national meetings, and has developed a career development plan) and only fund trainees at the post-doc stipend level who truly fit this definition.

Fundamental issues and challenges

As compensation for temporary career development training, NIH salary recommendations are sufficient for postdoctoral scholars in many regions of the country. However, in other areas of the US with high costs of living, an NIH postdoctoral trainee salary is a major hindrance to recruitment, retention, and overall quality of life in academic research. Thus, I agree that post-doc salaries should be increased in general, but not for everyone. My post-doctoral institution was based in the San Francisco bay area, which is one of the most expensive locations in the nation. Multiple data sources indicate that the cost of living in this region is double the national average. However, a post-doc in San Francisco, California receives the same stipend as a similarly experienced post-doc living in Manhattan, Kansas. This is not equitable.

Recommendation: I recommend that the NIH revise the current flat rate system for NIH stipends. Stipends should be adjusted based on regional cost of living.

Existing NIH policies, programs, or resources

The current T32 and F32 post-doctoral programs are excellent training opportunities because they require that the institution or PI of the trainee has developed an adequate career development plan. Applicants must provide evidence that a pathway to research independence for the post-doc is possible. I was fortunate enough to be funded by a T32 during my post-doctoral training. There is room for improvement, however, in these training programs. For example, some PIs still "cheat"the system with T32—and F32—trained fellows by not following through with the training opportunities that were promised in the grant proposal.

Recommendation: I recommend that these existing programs be modified so that yearly progress is scrutinized more carefully and more strongly tied to continued funding.

Proven or promising external resources or approaches

enhance the postdoctoral training ecosystem, because it enhances the diversity of the post-doc workforce in the country. As a PI, my lab would not survive without international post-docs, but without NIH-support, it is difficult to sustain them.

Recommendation: I recommend to expand NIH-funding to international post-doc scholars.

Response 1758

Perspectives on the postdoc roles and responsibilities

I view a postdoctoral position as a time where I can develop my own independent research under the mentorship and support of a more established scientist.

Fundamental issues and challenges

At the end of the day, money is a large contributor to the 'leaky pipeline' in academic research tracks, as trainee stipends do not adequately support the demands that are placed upon them at a vulnerable stage of their career. I am currently ending my PhD program and cost of living versus postdoc salary limits where I would be able to go as the current sole provider for a family of 4. A postdoc salary in a small midwestern college town (where I'm currently living) is decent to live on, but the same salary is simply a joke when considering larger costal cities.

Existing NIH policies, programs, or resources

As I've talked with advisors and academics in the field, a common expectation among training grants (F and K awards specifically) is that upon completing their PhD, trainees need to uproot their lives and move to a new institution to receive adequate training. Constant instability is another contributor to the 'leaky pipeline' as trainees are forced to leave their support networks over and over at a vulnerable stage of their

careers. I would create a some sort of funding mechanism to support postdocs that are wanting to continue in a scientific career at the same institution from which they obtained their PhD.

Proven or promising external resources or approaches

No response

Response 1759

Perspectives on the postdoc roles and responsibilities

Our role is to be independent researchers, help train graduate students, and aid in grant writing.

Fundamental issues and challenges

Money. My graduate school stipend was $38,000 at WashU in St. Louis. After taxes as a postdoc in Massachusetts, I make $39,000, and the cost of living is higher, so my net profit is less then it was in graduate school. Why would I stay in this position that clearly doesn't value me any more then a graduate student. To be frank, it's embarrassing to have a doctorate and have to turn down social outings with friends because you can't afford it. Lack of money also prevents postdocs from starting families—so it feels like you have to choose between having a family, or finishing a postdoc. And this isn't far from the truth. By the time most people finish their postdocs, they will be an age where a pregnancy would be considered a "geriatric pregnancy." So, people need to have a child in their postdocs years, but can't afford it. So, increasing pay and childcare benefits would help retain postdocs, especially women who are dramatically underrepresented at the PI level.

Existing NIH policies, programs, or resources

Postdocs need retirement benefits and child care aid as well as a large increase in the minimum pay.

Proven or promising external resources or approaches

Recruitment, training, work environment and mentoring are all completely fine. Please do not let the outcome of this survey be classes or tutorials that postdocs have to complete. Just increase pay for postdocs.

Response 1760

Perspectives on the postdoc roles and responsibilities

While the postdoctoral experience is not entirely without value, the additional time of scientific experience is not well valued in industry, and how useful a postdoc is to that career track is highly variable. Indeed, postdocs even more than graduate school are so HUGELY varied in nature, it is challenging to evaluate what that experience phase contributed to each individual.

Fundamental issues and challenges

Quality of life is the number one reason for dropping out of the postdoctoral career track. The hurdles to academic success have become so enormous, that the long hours of work, painfully low pay, and risk of long-deferred reward for this suffering make it nearly untenable unless you have another source of financial support. This promotes inequity in the viability of an academic career (those without more significant financial resources are unlikely to be able to afford the being a postdoc, and this will track strongly with disproportionate impacts on underrepresented minorities), or forcing those who would otherwise be promising academics to choose between career and starting a family. This financial disparity is the most problematic in the areas of the country in which some of the most prestigious academic training institutions are located, exacerbating the financial struggles associated with a postdoc career.

Existing NIH policies, programs, or resources

More significant financial support, specifically for housing and childcare costs, would undoubtedly make a significant impact on the retention of individuals in postdoctoral training programs. When I transitioned from a postdoc to industry in the same geographic location, my salary nearly tripled. In addition, my working hours were about 1/3 less. The science in industry was extremely focused and practical, not only aimed at the next CNS-publication-worthy discovery that would be relatively impactless nonetheless, beyond a niche scientific sphere. It made me wonder why I spent such an insanely long time in academia

before making the transition, as the challenges of being a faculty member have also become enormous in recent years. I've watched many extraordinarily talented colleagues and friends struggle intensely to succeed in academia, with no guarantee of success.

Proven or promising external resources or approaches

No response

Response 1761

Perspectives on the postdoc roles and responsibilities

The post-doc is something that is critical for a scientific career although many are not able to complete one due to financial and personal reasons.

Fundamental issues and challenges

Financial constraints are one of the biggest challenges with the post-doctoral fellowship. The very low salary and the restrictions on working to earn additional money were one the primary reasons I and many of my colleagues were not able to complete a post-doc. The salary is not a livable salary even for one person, let alone those who might have children or dependents in their care. This is a major proponent of disparities in who can and who cannot afford to complete a post doc. In today's world, many people have to work while completing degrees unless you are fortunate enough to have come from a privileged background, or you married someone with a lot of money, or you have a person who is giving you money to support daily expenses. Therefore, anyone from a lower SES or who is self-supporting (or has a family to support) cannot participate in a post-doc, widening the disparity gap between SES (all races and ethnicities), races (e.g., non white), ethnicities (e.g., non-latinx), and genders (women). The traditional academic viewpoint that you cannot work while completing coursework or pursuing a research career is antiquated and continues to be a major proponent of these issues and continues to support rich white persons who already have many advantages. This is hindering the diversity in our science and thought. This is also widening the gender gap and significantly limits the future scientific career of many bright and well-deserving scientists.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

One approach to inform is to connect with individuals who did not complete or were not able to consider a postdoctoral fellowship as a viable option. Understanding the reasons why Ph.D. prepared scientists did not complete a post-doc would give great insight into the issues from the perspective of the target group. Perhaps a national survey that could be facilitated by academic institutions would be a consideration.

Response 1762

Perspectives on the postdoc roles and responsibilities

I see postdoctoral studies primarily as a way for graduate students to obtain the additional research experience and training needed to succeed as an independent investigator in an academic/NIH R—grant situation. I don't think postdocs are needed in industry where a Staff Scientist position is more appropriate.

The roles and responsibilities of an academic postdoc are:

1. Lead a project under the supervision of a PI;
2. Mentor undergraduate and graduate students;
3. Develop an independent project that is distinct (although) related to their PIs funded work;
4. Write a K-award with mentorship and guidance from the supervisor and the institution;
5. Receive training in laboratory management, personnel management, scientific ethics, and academic interviewing with the goal of applying for and obtaining an independent academic position.

Fundamental issues and challenges

Fundamental challenges are:

1. Competition for NIH funding for postdoctoral K-awards and subsequently R—awards is high and is often seen as a barrier that many postdocs decide is not worth the effort.
2. Salaries and benefits in the private sector are often significantly higher than postdoctoral stipends in academia. Many PhDs see academia as a risky choice for their financial well-being and are able to find well-paying jobs outside of academia.
3. The success rate for postdoc-to-faculty transition is low and always has been.
4. Postdoctoral positions in many Universities are treated as temporary employment with annual reappointments being dependent on available funding—this job insecurity can be very stressful. Almost all postdoctoral positions within academic institutions are funded on 'soft' money where the PI and not the institution has to provide the guarantee of continued employment (most PIs feel like struggling small business owners that are trying to run a franchise!). As a consequence most postdoctoral positions in academia do not come with any retirement benefits. Many postdocs feel they are non-entities within the administrative environment of a large academic center.

Existing NIH policies, programs, or resources

1. Link the F&A and indirect costs paid on R-awards to Universities to their commitment to supporting postdoctoral benefits.
2. Expand the K-99/R00 programs, but cut the K-22 awards. The rationale being that no one should spend longer than 5 years in a postdoctoral position (K22 provide funding for those up to 8 years after their PhD).
3. Leverage R-awards by asking for institutional commitments to supporting postdoctoral trainees if budgeted. An institutional commitment might be provision of negotiated health care, inclusion within retirement benefits programs, provision of training with guaranteed time provided to undertake such training (grant writing, pedagogical training, personnel management etc), provision of affordable postdoctoral housing, etc).
4. Increasing the NIH-mandated stipend levels for postdocs such that they are competitive with the private sector OR provide more access to LRP for postdocs.
5. Increase the modular budgets of R-awards and the budget limits for non-modular budgets to allow postdoctoral scientists to be paid at higher stipend levels.

Proven or promising external resources or approaches

No response

Response 1763

Perspectives on the postdoc roles and responsibilities

As a researcher in the field of cognitive neuroscience, the postdoctoral training period is an invaluable time for people early in their career to gain additional skills, bolster their CVs with publications, and hopefully carve the way forward to launch themselves into an independent career. Having seen the CVs of people who have either skipped postdoctoral training, or who had extremely short postdoctoral periods (< 1 year), these people are at an extreme disadvantage relative to those with 2+ years of postdoctoral experience under their belts when applying for federal grants, faculty positions, etc.

Fundamental issues and challenges

When someone graduates with their PhD, their student loans come out of deferment shortly thereafter and those payments can be enormous. I had relatively few loans from my time in graduate school (~$3k per year for 5 years to cover my fees), but I also had loans for my time as an undergraduate (~$32k total in principal taken out over 4 years). By the time I finished my schooling, my loans exceeded $60k with interest, and the payment was an astronomical portion of my small postdoctoral salary ($42.5k annually), and I didn't qualify for IDR repayment plans because my husbands income pushed us just over the edge of eligibility.

Aside from loan repayment, as a woman in academia, child bearing was a difficult journey. I was pregnant when starting my first postdoctoral fellowship and had no paid leave time (not even sick time) when I left for maternity leave. Even though I was suffering postpartum depression and was still dealing with my physical recovery after delivery (I had some post-delivery complications), I had to return to work after 6 weeks of unpaid leave because my family honestly could not afford for me to take any more time off. I nearly quit in that period because I was so unsupported by my work, and I was truly struggling mentally, physically, and emotionally.

Existing NIH policies, programs, or resources

Parents, not just mothers, NEED paid leave time as part of the NIH policy, plain and simple. Mothers need time to heal and recover, and fathers need time to be equal partners and contribute fairly to care responsibilities.

The Loan Repayment Program is wonderful for alleviating the burden of student loans, but it is extremely competitive and takes quite some time just to review, let alone get funded. I know many scholars apply multiple times before getting funding. There should be additional considerations for loan repayment/forgiveness for postdoctoral scholars, and/or higher pay to accommodate the debts that so many face when exiting graduate school, which is a notoriously low-paid period.

Proven or promising external resources or approaches

The loan repayment program is an outstanding resource that should be publicized to a greater degree, and should probably have greater funding to allow more scholars to take advantage of the program. Quality of life improved for people across the US when student loans were frozen in 2020.

Professional conferences/meetings have started adopting parent-friendly policies like offering care grants, or having childcare resources on site at the meeting. Having parent-forward policies increases participation and creates more equitable environments for people of all backgrounds and extramural responsibilities to continue progressing their careers.

The US broadly needs better parental leave policies. Having adequate PAID and PROTECTED parental leave improves job satisfaction, fosters healthier children, and improves participation in the workforce among women.

Response 1764

Perspectives on the postdoc roles and responsibilities

A training for me to learn multiple techniques, communication skills, and independent thinking, and to obtain opportunities to learn how to write grands, how to run a laboratory.

Fundamental issues and challenges

A lot of reach field have extremely limited funding sources. It looks like the distribution of grand leasing is too political, rather than scientific. In my postdoctoral trading, sometimes I need some financial support based on the city I live from my parents.

Existing NIH policies, programs, or resources

Limited grand sources, poor salaries for postdoctoral researchers, citizen bias.

Proven or promising external resources or approaches

Money is the core point. The level of fundings for academic from organizations or governments and the financial support for industrial research and development from their own are hugely different, as a result, postdoctoral researchers earn less money than employees in industries. The unfair salary for postdoctoral researchers is a direct cause for them to choose an industrial job.

Response 1765

Perspectives on the postdoc roles and responsibilities

I am expecting to acquire new competences and be mentored.

It is often mistaken that we as postdocs shouldn’t be training and learning.

Fundamental issues and challenges

Housing in NYC is a real issue impacting the quality of life, and should be treated as so.

Academic institutions should either increase the compensation or find appropriate housing with rents below the market.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1766

Perspectives on the postdoc roles and responsibilities

My understanding is that a postdoc prepares the person to become an independent scientist. Postdocs are supposed to publish as many papers as possible so they are competitive.

Fundamental issues and challenges

I am choosing not to do a postdoc because why would I waste another 2-3 years of my life with low pay just to enter academia which also has low pay. Why would I waste my time doing a postdoc if positions in academia are so competitive? What if I don't get tenure? Entering academia is not worth it. You don't have job security, you are paid a low salary, you have to deal with the outdated culture and politics in academia, and you work so hard that your job consumes you. It's not worth it. I would rather get a decent paying job with my PhD than continue to rot in academia.

Existing NIH policies, programs, or resources

Pay postdocs a livable wage. 50-60k (sometimes 40k) is not enough. A highly educated, competent, and driven individual does not deserve to get paid so lowly. Also, stop giving NIH funding to old tired professors that need to retire. There are too many candidates for academia and not enough positions in the U.S.

Proven or promising external resources or approaches

The culture has to change from within, starting with the people who have power. If they don't change (e.g., stop being racist, sexist, transphobic) then replace them with more empathetic and informed people. You can't just recruit more "diverse" postdocs and expect the culture to magically change. Put people from historically-excluded groups in positions of power. Enact policies that protect people who aren't in positions of power. I think graduate students and postdocs are the bread and butter of academia. Our PIs would be nothing without us, and it's time we get some respect. We need good pay, vacations, parental leave, benefits, and excellent insurance that doesn't exclude teeth and eyes. I want the academic institution to start treating its postdocs like the intelligent and capable individuals they are, by giving them incentives to stay in academia, rather than continuing to exploit them. Otherwise, people like me will continue leaving academia in droves.

Response 1767

Perspectives on the postdoc roles and responsibilities

Training for new skills or advancing the phd training

Fundamental issues and challenges

Bad pay; expectation to be autonomous with no support (postdoc by definition is trainiee position so we do need "training"); expectation to relocate to job location when the salary is so low (cant uproot our families for this)

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1768

Perspectives on the postdoc roles and responsibilities

post-docs are the driving force behind a lot of the research done in labs. They serve as both a tutor for graduate students while they have the memory of grad school fresh in their minds, as well as a more direct equal to the lab PI to more rigorously pursue research projects.

Fundamental issues and challenges

The pay of a post-doc is the main concern that's causing me to consider a position in industry rather than academia post-grad.

Existing NIH policies, programs, or resources

Increase base pay for post-docs. Potentially increase ease of access to NIH resources for more opportunities for collaboration/to expand the potential for post-doctoral research into translational science for those working in labs focussed on "basic" science. Access to patient samples, etc. It's the wealth of resources available in industry that's also tempting for young researchers.

Proven or promising external resources or approaches

Increase funding for post-doctoral training activities i.e. increasing subsidization of post-doc travel to NIH organized symposia and training events. Create more of these events. This way one will not have to join a well funded lab to be able to attend additional conferences or gain access to all the resources they might want or require for their research and training.

Response 1769

Perspectives on the postdoc roles and responsibilities

The last training step to be able to conduct research as a leader.

Fundamental issues and challenges

The stress to do well is constant. Not only for your future, but also the present (being able to financially support family, housing, health, etc.). In addition, there is the stress of getting a position of interest in the futurre.

Existing NIH policies, programs, or resources

There should be a review/evaluation of the Principal Investigator by his/her students and postdoc in an anonymous and protected way. This would be a great way to be aware of PIs that are not treating the subordinates fairly.

Proven or promising external resources or approaches

First is being able to provide a descent salary (this can vary according to location cost of living). Second, as mentioned before, 360 degrees evaluation is needed.

Response 1770

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

Pay remains an important consideration, perhaps especially for physician trainees. At my institution, the mandated salary scale for physician trainees vastly exceeds the NIH-provided stipend for T32 trainees, creating a very large salary gap that needs to be covered by other intramural means. This creates important challenges to the viability of T32 programs.

Existing NIH policies, programs, or resources

Mentoring is another ongoing, critical challenge. Within the aging research community, the NIA-funded Clin-STAR program has played an important role in addressing this issue, but it's the tip of the iceberg. Mandatory trainings or requirements are unlikely to be effective, but providing more robust resources to help program directors and postdocs understand how best to work with mentors, develop and implement individual development plans (IDPs), and create guardrails to optimize the mentoring experience would be very valuable.

Proven or promising external resources or approaches

See comment about regarding the Clin-STAR program. UCSF has some excellent resources around postdoc mentoring and resources such as model IDPs—see https://career.ucsf.edu/welcome

Response 1771

Perspectives on the postdoc roles and responsibilities

Postodoc position for me is about professional and scientific growth and an opportunity to hone current skills and develop new ones

Fundamental issues and challenges

The biggest challenge for me was getting funding. So many funds are available for 'Early Career Investigators,' but only some allow postdocs to apply as Principle Investigators. Postdocs are at the career stage where they need maximum support to grow and continue in academia. This includes but is not limited to grant writing seminars/workshops, conferences, and meetings specifically emphasizing travel grants for postdocs to present scientific findings. Apart from this, more NIH-funded awards/training should be available to and reserved for postdocs only. I firmly believe that without this support system, postdocs will not be able to survive in Academia, and Academia will loose talent.

Existing NIH policies, programs, or resources

Make small grants such as R03, and R21 eligible for postdocs to apply as Principal Investigators.

Proven or promising external resources or approaches

No response

Response 1772

Perspectives on the postdoc roles and responsibilities

I strongly believe that the postdoctoral phase is a critical period for professional and personal growth as a scientist, where individuals can develop their independence and maturity. However, it is important to acknowledge that this is also a transient position, and postdocs need support to ensure they can successfully transition into their next career stage.

To ensure that postdocs are supported and have equal opportunities for professional growth, it is imperative that measures be put in place to prevent any unfair practices or exploitation. The best possible solution is to assign anyone that is paid by the NIH funding a mentoring team to provide them with guidance and support outside of their direct supervisor.

They should require early stage scientists from all levels that are paid for 6 months or more in anyone's lab should always be reported to the NIH and the NIH should enforce PIs especially if they want those tax payer dollars that they need to also have to support trainees and not just say it but the NIH should mandate all trainees have a mentoring team in place. This will create a transparent and healthy environment where everyone is checked through their trainings. I bet that this will avoid all kinds of messed up ethical issues that cost the NIH billions a year on wasted labs from all the fabrication [redacted] that they pull. It will also give the PI another pair of eyes that are so looking at them so that they don't pull anything shady.

Fundamental issues and challenges

For starters, the pay is terrible, absolutely horrible! It is impossible for anyone with a family to live off it, unless you can supplement it with welfare or EBT money. Why would anyone want to work and be poor for

the rest of their lives? This is especially true for minority trainees who usually do not have any generational wealth but have many family members to take care of.

It is not possible to survive on a postdoc salary. So, why subject yourself to unnecessary poverty? What is the point? On top of that, the PI mistreats you, and when you complain to the Chair, you get a [redacted] answer. Especially if the PIs have multiple R01s, which means they are bringing in millions of dollars in indirect costs. The Chair and deans will then of course will look the other way.

Existing NIH policies, programs, or resources

The NIH bears a lot of responsibility for perpetuating this toxic culture. The issue of potential competition between postdocs and their bosses is also a serious concern that needs to be addressed promptly. The prevailing mentality is that postdocs need to do something different from their bosses for the R00, but why? Instead, why not promote a collaborative and supportive mentoring environment that allows scientists to evolve and flourish organically? This approach would encourage discovery. No one discovers anything by themself!!!! It is crucial to establish a workplace where postdocs can collaborate with their supervisors. The NIH should actively encourage this approach instead of promoting the R00, which encourages postdocs to differentiate themselves from their PI. This is not a competition. Such attitudes only contribute to burnout.

The NIH has to promote a healthy environment a collaborative one, one in where if you do continue to work with your mentor that it is rewarded this way PI would be encouraged to work with their postdocs and postdocs don’t have to do side hustle experiments that they need to propose differently for the R00 without the PI knowing. Everyone I know does this. They all have to sneak experiments for their K99 applications to be competitive.

Proven or promising external resources or approaches

The NIH needs to provide childcare expenses. A system should be in place where trainees can submit receipts for daycare expenses and receive reimbursement or a stipend.

There should be a system in place that allows trainees to provide feedback about their PIs and R1 institutions. A separate survey or grading system should be filled out by trainees to evaluate the training environment at their institution. This approach would give the NIH an idea of how supportive institutions are towards their trainees. To maintain their R1 status, institutions should receive a passing grade, and if the grade falls below a C, the NIH should not provide funding for that institution in the following fiscal year. This approach would encourage institutions to address issues such as unethical practices and toxic training environments. No institution wants to be publicly known as a toxic place, as it could negatively affect their reputation and donations.

The promotion of mentoring teams for trainees should be mandatory and should not be limited to the same approachable faculty members.This places an undue burden on them. Instead, the NIH should mandate that all PIs be on a mentoring team.If you receive funding, you should also give back.This would require everyone to sign up, not just the few who always volunteer to help out. It is frustrating to see PIs who have the luxury of focusing solely on their research while others struggle to help out trainees and early-stage faculty.

Fortunately for me, what worked was that I had to form, or was encouraged to form, a mentoring team for my transitional grant. This helped me tremendously because it was highly encouraged, and my PI did not become paranoid since it was a requirement.He knew that if he wanted me to pay myself off his grant, he would have to be supportive.

Response 1773

Perspectives on the postdoc roles and responsibilities

Postdoctoral position is an opportunity to publish one’s own research, with support of an established lab, to test and prove both interest and competency in the research profession.

Fundamental issues and challenges

I fielded responses from friends and colleagues who did not enter in academia: these views also reflect my own

1. Poor job market: sense that more PhDs are produced than academic jobs available
2. Low pay and opportunity cost in taking postdoc positions relative to other career choices
3. Changing landscape of academic culture: off-putting identity-centered culture—explicit yet illegal identity-based hiring practices and discriminatory rhetoric by university officials discourages many from remaining in academia

Existing NIH policies, programs, or resources

1) EXPAND: Information of job market and hiring outlooks for industries and professions with potential forecasting to help students make informed career choices (other career resources provided by NIH are clear and helpful, but actual market data would be a definitive help)
    a) e.g. A real-time heatmap of collated academic job postings across US (a student could have a visual idea of how many jobs are available at a given time and where they are available)
2) IMPROVE: More competitive funding for student stipends
3) MODIFY: Perhaps have mentoring new researchers as a component of NIH grants for academically-inclined postdocs—many graduate students complain about poor mentorship from PIs, but do many take mentoring seriously in their academic training?

NOTE: The NIH's diversity guidelines and definitions are clearly defined and thoughtfully laid out, giving concerned persons of various backgrounds confidence in fair assessments.

Proven or promising external resources or approaches

No response

Response 1774

Perspectives on the postdoc roles and responsibilities

I view a postdoctoral position as an opportunity to continue training for someone who wants to lead their own research group. Additional training in a new system, new techniques, getting preliminary data that would be basis of starting one's own group. More mentoring and teaching opportunities as well. I had the sense that historically it was optional, but slowly came to be the norm for those wanting their own group (mainly due to competition). I had the sense that these were typically 2 years, versus now the close to 5 year for some.

Fundamental issues and challenges

For those that at one point consider wanting to lead their own research group, the competition for jobs is daunting and exhausting and may not pan out. This reality is discussed more openly now at the graduate level so many are carefully considering their career moves with this in mind. Also, there are more industry jobs and bioinformatic jobs then before, and I feel there are many who go there. Some are juggling partners and young families and moving somewhere for a couple of years, in some cases with support only guaranteed year to year, is hard. Support in starting a family or raising young children varies widely not only institution to institution, but PI by PI. Just work-life balance in general—some PIs can be very balanced, but some can pressure PDs to work around the clock to produce data. I hear pay can be an issue, but that varies widely geographically. 10 years ago when I was first a post-doc, I remember feeling I had completed an advanced degree and still was getting paid just over $32,000. I justified it as this was more "training", but really PIs were using the "training" to having skilled hands at low cost. Some of this is grant driven with only so much money, but it felt like why get a PhD?

Existing NIH policies, programs, or resources

So much has been done for the better in the last 5-7 years I feel, but some of those feel initiated by my own institution. There is a center for post-docs and they run workshops on resumes/CV, teaching modules, ways to find jobs outside of academia, a confidential way to report abuse, etc. Increases in pay, but there seems to be stories out there about institution (university/department) red tape. Sometimes a PI wants to

pay more or offer a contract longer than a single year, but rules prevent that. I've been happy to see more conversations at the graduate level, so those that go into a post-doc know the purpose and end goal. Those not interested in running their own lab shouldn't start a post-doc.

Proven or promising external resources or approaches

I just want to put in a plug for creating and normalizing a staff scientist position within a research group. I do not want to run my own group, but I love bench work. I bring expertise to my group, and help the PI with training of students and providing continuity in the lab. At my institution, after some time as a post-doc you are automatically elevated to research associate. However, our grant can't always cover the minimum compensation level so we've had to get creative. So many labs and individuals would benefit from this structure. You wouldn't have as many graduate students (but again, there are not enough academic jobs for them all anyway) and the personnel costs would be higher, but academia was built on the backs of the students for so long that it needs to change.

Response 1775

Perspectives on the postdoc roles and responsibilities

publishing work, conducting science in a more independent way, mentoring and training students as needed, training opportunity to build independence and skills in grant writing before transitioning to faculty position. opportunity to broaden scientific background and skillset before establishing own lab.

Fundamental issues and challenges

MONEY. Postdoctoral trainees do not make livable wages, especially when compared to industry positions, and particularly in regions of the US where top institutions are located (California, New York, etc.). Timeline of training. Doing 5-7 years of a PhD and then 5-7 more years of a postdoc places individuals well into their adult life and delays personal decisions like buying a home or having children. Academic barriers. IE, seeing junior faculty struggle and how difficult it can be do get grants and manage all of the responsibilities with minimal training in managing conflict, budgets, etc. Competition. It is becoming more and more difficult to land grants and jobs and the bar continues to climb higher. If you aren't willing to sacrifice then it is unlikely you will succeed and many aren't willing to make this sacrifice. Climate and equity. There are still discrimination issues within academia, and these can accumulate and become unbearable, particularly amongst marginalized groups. NIH needs to hold faculty accountable for creating equitable spaces. It is unclear to me why faculty with a proven trackrecord of sexism, harassment, etc. would continue to receive NIH support and maintain an ability to mentor students and postdocs. There has to be a money motivator to promote "good behavior." Work life balance. It feels impossible to maintain cutting edge status in science while also enjoying a personal life.

Existing NIH policies, programs, or resources

Provide more funding opportunities for postdocs, even short term grants or partial salary. Increase the NIH payline for postdocs, particularly in regions with higher cost of living. DEI programs and faculty training for interacting with postdocs and diverse individuals. Hold faculty accountable for providing mentorship in equitable ways to postdocs. Increase funding going to junior faculty and toward transition grants so that young PIs can establish themselves. Decrease funding going toward inactive labs with faculty of retirement age, perhaps by monitoring spending and productivity more closely for PIs with multiple grants, centers, etc.

Proven or promising external resources or approaches

No response

Response 1776

Perspectives on the postdoc roles and responsibilities

In the culture of the united states, as compared to the Netherlands, treats both graduate school and postdoc as training positions. However, the nature of the work, and the expectations of what it takes to get these positions, has changed drastically in recent decades to the point where both positions are decidedly employment positions despite the appearance of flexibility. Post docs are expected to produce scientific products at a rate that is equal to or greater than a tenured professor. They do get some training

and support, but this training and support is roughly equivalent to a mid-level manager, or senior-mid-level manager in industry. Often they are fully responsible for desiging and executing studies with minimal oversight. They mentor and train in a way that is hardly distinguishable from assistant professors, and often more involved in day-to-day lab activities than tenured professors (obviously, there is variability). In other words, it is no longer a training position; it is a collaborative research position with some on-the-job training.

Fundamental issues and challenges

Research budgets must expand to provide postdocs with competitive salaries and benefits. In my understanding this must come from congress. Moving expenses, or remote-work options must be provided. Training and support for transitioning to non-academic positions must be provided. Finally, post-doc supervisors must be accountable for exploitation and mistreatment. This is not perfect anywhere, but the current model of what is essentially a principal investigator's feudal fiefdom leads to extreme vulnerability for post-docs. PIs may essentially control a post-docs career prospects.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1777

Perspectives on the postdoc roles and responsibilities

Training position to learn how to apply knowledge in new environment and expand skills necessary to succeed in either academics o industry or other field. Time to expand horizons, whether that's new technical skills, writing grants and papers, net-working, etc.

Fundamental issues and challenges

Few well qualified applicants since so many other higher paying opportunities.

Usually stay once see value in experience, so retention is not as much of an issue.

Work/life balance is considered, but it's hard to offer high enough salary in big cities

Existing NIH policies, programs, or resources

Higher budget for postdoc, and therefor grants.

More opportunities for networking, presentation, etc and carrots that value this so applicants see the value in the training.

Proven or promising external resources or approaches

Have complemented with industry CRA's to help fund and provide added exposure

Response 1778

Perspectives on the postdoc roles and responsibilities

My postdoc term is an opportunity for me to explore challenging scientific problems using the experience gathered during my Ph.D. It also offers an opportunity to collaborate, mentor, and engage with the scientific community. I also consider it a transitory period toward my career as an independent investigator.

Fundamental issues and challenges

Firstly, increased salary, which is the basic and most urgent change in the current system of postdocs. The annual increase of a postdoc salary is very marginal and does not account for the growing inflation and the high cost of living, especially in bigger cities in the US.

Secondly, social security benefits like retirement 401(k), child care, and paid maternity leave really make working in academia an unsustainable choice. This is especially relevant as many postdocs around the

ages 27-35 yrs think of starting a family during these crucial years and without the benefits, it becomes really difficult to make ends meet. A lot of us look for other high-paying alternative career choices just because we feel overworked and underpaid. Thirdly, for postdocs on a visa, the opportunities for grant application and awards are limited (due to the application criteria).

Existing NIH policies, programs, or resources

It would be great to have an increased salary. This will also help to incentivize postdocs and hopefully retain them in academia afterward (as PIs). There has been an increasing trend of postdocs or even grad students seeking job opportunities in the industry or other high-paying sectors because they feel undervalued and underpaid for the time and efforts they put towards academic research.

The postdoc fellowships can be made available to postdocs on a visa.

Proven or promising external resources or approaches

No response

Response 1779

Perspectives on the postdoc roles and responsibilities

Postdocs are in training to gain additional scientific and mentoring skills to allow them to pursue either academic or industry scientist positions.

Fundamental issues and challenges

Postdoc pay is a major factor currently, particularly in high cost of living areas such as Seattle, where I am located. Many grad students are going straight to industry because they do not want or can’t afford to live on a postdocs salary. Particularly if they have children, it is very difficult.

In Washington, we have a new minimum wage law where minimum for salaried (exempt) employees where current Y1 postdoc salaries are over $65,000. In 2-3 years, that will need to be $90K per state law. While that is great for postdocs trying to live in an expensive area. That is very hard on your R01s to cover those salaries. Perhaps the NIH could make modular R01s up to 500K and then have itemized budgets over that.

Existing NIH policies, programs, or resources

NIH postdoc salary scale needs to be adjusted upwards or be tied to cost of living of the area. Easy to access funds for postdoc childcare as supplements to F32s or for their PIs R01s.

In Washington, we have a new minimum wage law where minimum for salaried (exempt) employees where current Y1 postdoc salaries are over $65,000. In 2-3 years, that will need to be $90K per state law. While that is great for postdocs trying to live in an expensive area. That is very hard on your R01s to cover those salaries. Perhaps the NIH could make modular R01s up to 500K and then have itemized budgets over that.

It is also very difficult now for us to supplement the stipend of postdocs on F32 or T32 grants since their salaries are well over the NIH scale in WA, but we need to supplement with non-federal money. Why can’t we supplement with federal money. Many of us don’t have access to much non-federal money for these purposes.

Another very important issue is that postdocs on F32s are not allowed to be employees of our institution by NIH policy. This makes it a penalty for postdocs to be on an F32--they lose their retirement benefits at a time when this is key. We also have to have a very complicated workaround for postdocs to keep their health insurance and other insurance policies even though they become non-employees, creating administrative headaches. They also lose access to state FMLA, which is important for unforeseen medical issues or for parental leave after birth or adoption, because they aren’t paying into the system as non-emloyees. WA state FMLA is very generous.

Proven or promising external resources or approaches

1) Allow postdocs on F32s to remain employees (and pay indirects on F32 grants).
2) Increase the salary scale or have the salary scale vary by cost of living of the area.
3) Childcare supplements
4) Allow F32s to be more than 3 years, particularly for postdocs who want to stay in academics. K99 or K01 or K22 awards are very hard to get. Or just have more K awards available for postdocs to allow them a few extra years. It takes a 5-6 year postdoc to get a good academic job. But PIs can't always support a postdoc for that long.

Response 1780

Perspectives on the postdoc roles and responsibilities

To perform semi independent research with oversight by mentor with knowledge of the literature and incorporation of new ideas. Mentor responsibilities include training of post-doc in presentation skills, analysis of data and visualization, writing manuscripts, fellowship application, critical review of papers. Mentor can provide career advice or referral to relevant persons, opportunities to supervise other personnel, and importantly, support and encouragement.

Fundamental issues and challenges

The availability of qualified individuals seeking academic post-docs have plummeted in recent years. This is likely due in part to the COVID-19 pandemic which has limited travel and the desire to be away from family. However, I think the difficulty of an academic position in terms of funding and lack of job security has had a huge impact on the field. Retention is affected by availability of jobs in biotech paying much higher salaries or a desire to move to a non-research based trajectory.

Existing NIH policies, programs, or resources

The biggest thing the NIH can do to make academic post-doc positions more appealing is to pay higher salaries. This also impacts the ability of faculty to fund post-docs because the NIH salary limits don't cover the actual salary of post-docs. For example in WA State, post-docs are now required to be paid a minimum of over $65K per year, not including fringe. Thus, our grants are not covering full salary and it may mean we are unable to hire enough staff for the proposed work.

Proven or promising external resources or approaches

Required training for investigators requesting funding for post-docs on grants that defines training and mentoring requirements and instructs investigators on how to foster a supportive work environment. This could be part of the JIT materials. There may also be a way to require institutions that accept NIH funding to require this for all investigators to cover post-docs that are paid through non-NIH funds.

Response 1781

Perspectives on the postdoc roles and responsibilities

A postdoctoral position is a very important transition position between PhD completion and independent research leadership. It the best period to acquire a deeper knowledge and training on biological background, biology and techniques for developing a research project, explore new perspectives. However, it's also the moment to learn additional skills fundamental for a future PI, such us student supervision, grant writing or networking.

Fundamental issues and challenges

Postdoctoral positions require high levels of training, effort, dedication, and resiliency. A so demanding position with these requirement is generally well appreciated and compensated in other professional fields. However, postdoctoral researchers in academia are incredibly underpaid. Salaries are ridiculously low comparing similar positions for similarly trained people in industry. First-class academic research institutions are generally located in big and expensive cities. Therefore, low salaries became an issue from the very beginning of the postdoctoral period. Moreover, these difficulties increase exponentially if the person has dependents or comes from a foreign country, what adds more obstacles like visa processing.

Academic institutions do not provide enough mobility, housing or dependent care solutions. In addition, many postdoctoral researches suffer a toxic working environment with never-ending schedules, inexistent holidays or vacation days and disrespectful supervisors. With these unattractive job conditions, PhD graduates look for other alternatives in science after their PhD training, and postdocs look for well paid jobs in industry or move to other countries.

Existing NIH policies, programs, or resources

Increase salary tables, including a percentage of correction for expensive states/cities. This is something already implemented in European Union funding for postdocs like the MSCA fellowships where a country correcting is applied.

Proven or promising external resources or approaches

Force institutions to increase salary, compensate experience, provide housing and dependent care solutions, promote healthy work environment, provide protection against toxic PIs.

Response 1782

Perspectives on the postdoc roles and responsibilities

Its a good platform to try and develop new protocols and venture new research avenues and to be more independent.

Fundamental issues and challenges

Funding issues which affects the visa and other requirements makes it stressful, especially with contract renewal.

A stable employment position with a 3years or 5 years fixed position at the University with employee status would help.

Transitioning to young faculty could be made easier with special programs or facilities

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1783

Perspectives on the postdoc roles and responsibilities

A postdoc holds a senior position in a lab, and is responsible for both research as well as assisting in the training of graduate students. In my experience, postdocs may act as a direct mentor for a graduate student if their research areas overlap significantly, but more often postdocs act as experts on specific techniques on an as-needed basis.

Fundamental issues and challenges

Both money and negative experiences in academia are major factors that come up in my conversations with fellow grad students about the decision to pursue other options over postdoctoral positions. Jobs outside of academia can offer salaries that give financial security, whereas many postdocs only receive enough to live on fairly comfortably (~$55,000 is not uncommon), but not enough to feel secure. Since graduate school requires students to live on a very limited budget for 3-7+ years, with PIs who may require them to work 7 days a week/10 hours a day, many feel like they have reached a point in their life where they need to start being properly valued for their time and expertise. Especially given as postdocs may also be required to work extremely long hours and be expected to do things above and beyond their pay scale. I think that academia asks people to sacrifice a lot of things in the name of their passion for their research area, and people are getting so burnt out in their PhD that that sacrifice doesn’t seem worth it anymore. Especially when they receive reviewer comments that show that those sacrifices are still not good enough, and may never be good enough. Almost every journal club I’ve attended has had PIs ripping apart published papers and disparaging the conclusions. I think that to be seen as “productive enough” in

academia, you have to give up a good portion of your life, but the pandemic has shown us that the time we have with our loved ones is precious. You can't just put your life on pause until you one day become tenured, you have to be able to live your life now. That means that you need to have both free time and money.

Existing NIH policies, programs, or resources

NIH review sections could be better regulated so that reviewers who regularly are overly harsh in their feedback are no longer put into review sections. Especially when it is clear that the reviewer did not read the proposal.

Proven or promising external resources or approaches

No response

Response 1784

Perspectives on the postdoc roles and responsibilities

An academic postdoctoral position is effectively a research scientist job. My job is to work with the PI to conceive of and design experiments that advance the interests and scientific contributions of the laboratory, then carry out said experiments. Additionally, I mentor and manage graduate students, undergraduates, and other laboratory personnel as appropriate.

Fundamental issues and challenges

Salary to cost of living ratios are the root of most problems related to recruitment, retention, and life quality. This is particularly true in the light of what equivalent industry positions are able to offer. While it is not necessarily expected that academic salaries would ever match those of private sector equivalents, most of my colleagues that went straight from graduate school to industry are making double what the NIH standard salary is. Much of this also stems from broader laboratory/scientific funding (particularly large governmental grants such as RO1s) being entirely stagnant for decades. Without increased laboratory funding to keep up with general scientific and cost of living increases, the possibility of increased postdoctoral salary, or job security, is next to impossible. Similarly, few fellowships have stipends/salaries and supply cost allowances that match the actual cost of living and doing rigorous science, respectively, in most parts of the U.S.

Personally I also didn't consider applying to several postdoctoral positions at several prestigious labs in my field due to the cities these labs were in having a cost of living that was so outrageously higher than potential salary.

Existing NIH policies, programs, or resources

Again, scientific funding at the laboratory and fellowship levels seem to have largely stagnated for decades and is entirely uncoordinated with the US economy, local costs of living, and general cost of scientific expenses.

Proven or promising external resources or approaches

No response

Response 1785

Perspectives on the postdoc roles and responsibilities

I view the post doc as a transitional position where the goal is to be trained as a independent scientist. A post doc should be responsible for driving the project forward with minimal supervision from the PI.

Fundamental issues and challenges

The major challenge is the expectation of constant productivity driven by grant deadlines. The other issue is being compared to extremely old "permadocs" or really fresh post docs who have just trained in the " technique of the week". For example more emphasis is currently being given to post docs who have trained with computational techniques or high throughput ones such as mass spec. There is also an increased need for doing second post docs so that people can apply for faculty position. Also, grant

deadlines make it impossible for most people to try and fail. Results are expected immediately, reproducibly and accurately. To me this is most important issue leading to scientific misconduct.

Existing NIH policies, programs, or resources

A post doc position is temporary. There should be a hard deadline for post docs. The ones wishing to stay on in a similar role should be given a distinct title rather than associate or assistant and paid fairly. There should also be a hard deadline on faculty position like there is for most government jobs. This is create more opportunities for junior scientists to be promoted and not spend additional time looking for additional positions. The most important issue is that the individuals who are currently looking for post docs did not have to go through the same rigor and requirements that the current post docs have to face and this demoralizes most people on this "temporary job" market.

Proven or promising external resources or approaches

A post doc mentoring committee should be required for all NIH post docs.

Mental health counseling should be mandatory

Response 1786

Perspectives on the postdoc roles and responsibilities

Academic postdoc training allows advanced research training with graduated responsibilities, including increased independence, opportunities for leadership and mentorship, and increased exposure to the roles and responsibilities of next-level job opportunities in academia or industry. This time allows for building a portfolio of scientific and leadership strengths that are typically beyond the scope of a typical graduate student. Thus the postdoc is a transitory training role that may include protected opportunities to pursue high-risk projects with supervision. Interestingly, the importance of the postdoc has evolved with time, arguably in large part in response to market factors (e.g. inadequate faculty positions) without (to my knowledge) consensus codification of its role in the scientific enterprise, or deliberate organizational planning of its intended training role.

Fundamental issues and challenges

The destinations and paths of scientists post-PhD have changed dramatically. Incomplete understanding of these changes severely impairs academic PIs from effectively staffing labs and maintaining critical basic research, as well as effectively mentoring postdoc trainees. Certainly salary is a huge challenge, where compensation has traditionally been not commensurate with the level of specialization and expertise. Comparable remuneration of postdocs and mid-level technicians in academia does not support value. Altering this structure is highly challenging given the limitations of grant budgets. Competition by speculatively funded industry entities further challenges recruitment and retention of postdocs. It should also be recognized that postdocs are often at an age where they are contemplating starting families, which is further challenged by academic postdoc salaries. Cultural factors also hinder recruitment, including contemporary ideas of work-life balance. Overall, recruitment and retention of postdocs has become excessively challenging, and I believe that failure of the academic enterprise to address this adequately with a satisfactory long-term view will cripple US dominance in the biomedical sector.

Existing NIH policies, programs, or resources

Grant budgets need to reflect needs, especially to remain competitive internationally. We need a strategy that is sustainable.

Proven or promising external resources or approaches

No response

Response 1787

Perspectives on the postdoc roles and responsibilities

As director of a T32 training program, I see postdocs as future faculty in training. They are both employees doing work and in training at the same time. The same can be said of junior faculty with career development awards.

Fundamental issues and challenges

1) Postdoc salaries do not provide a living wage.
2) Paylines for T32 programs are not reported by all institutes and are overall too low (too restrictive). Postdocs are the lifeblood of future research capitol—we should encourage them rather than stifling them with poor paylines.

Existing NIH policies, programs, or resources

Postdoc salaries need to be increased to a living wage.

Proven or promising external resources or approaches

No response

Response 1788

Perspectives on the postdoc roles and responsibilities

The postdoc experience, as I understand it, is designed to allow individuals to

1. acquire additional skillsets beyond their graduate training,
2. master and utilize their existing skillsets to generate novel data in support of a K99/R00, and
3. function as the final step on the path toward independence.

Fundamental issues and challenges

The biggest issue that I see is the pay gap between the postdoc salary and positions the same individual would qualify for outside of academia. The entry level salary for an individual with a PhD is roughly 100k/year, effectively doubling the postdoc salary with no prior experience apart from the terminal degree. This problem is especially prescient now given that individuals are starting graduate school later in life and often take a year or two to work as a research specialist/technician, or in a postbac type of role, to gain the experience necessary to even enter graduate school (as the bar to entry is ever increasing). Furthermore, postdoc positions are routinely lasting for 5yrs before transitioning to a faculty position. The scenario presented above could be managed as a calculated risk, if the postdoc knew for certain that their time, effort, and financial sacrifice in pursuit of a research faculty position would be granted if the "recipe" were followed. But we know this is not the case. It appears that, at best, only 20% of postdocs will enter into a tenure-track position following their postdoctoral training. When presented with this scenario, why would a highly trained individual say, "yes, this sounds like a reasonable." We are scientists, we take calculated risks. I would assume that an R01 requesting 10yrs of funding with a projected 80% failure rate wouldn't even make it to study section.yet here we are as postdocs still fighting the good fight? The math here doesn't quite add up when you lay it out.

Existing NIH policies, programs, or resources

Clearly, the base pay is the greatest issue facing postdocs currently. Many postdocs are in their early/mid thirties and would ideally like to start a family at this time. However, this is a costly endeavor and, quite frankly, the postdoc position is a huge roadblock to this major life goal for MANY people. So, people are giving up one of the greatest joys in life for poor pay and no real guarantee of success in securing a faculty position.

While I would love to see competitive wages between industry and postdoc positions, I realize this would be a difficult task. However, blanket insurance policies for a spouse and dependents would help allow postdocs to actually start a life outside the lab. For example, base pay is currently 54k/year, which equates to roughly 4,250k/month after taxes/SS. At my current institution, health insurance through BCBS is $750/month for spouse+child (health and vision, NO DENTAL). Thus, take home pay ends up around 3,400. Now the current price to rent a home, as most individuals are forced to because they have not had the opportunity to save enough for a downpayment during graduate school, is roughly 2000/month. Thus, we are left with $1400 to cover utilities, groceries, gas, and internet for the month. It is quite literally just enough to make ends meet, but leaves no room for error. The take home message here is that a policy enabling health insurance (including vision and dental) to be covered for a spouse/dependents would allow the postdoc to keep a substantial amount of their salary and enable a family to live a healthy life.

Proven or promising external resources or approaches

No response

Response 1789

Perspectives on the postdoc roles and responsibilities

A temporary training opportunity before transitioning to a true career position. Depending on the individual's ultimate career goal, it may or may not be necessary.

Fundamental issues and challenges

Many issues that I'm aware of are tied to the visa challenges for many international scholars—PI's feel abusive with threats to fire and therefore end work-tied visas. Retention is less of a concern from my experience—the opposite is almost more concerning as some PI's try to force postdoctoral trainees to stay longer than necessary to ensure continued productivity for the lab (and to the benefit of the PI, rather than the benefit of the trainee).

Existing NIH policies, programs, or resources

Yes—frequently, the NIH established minimum for postdoctoral salary is seen as the guideline. Resources are also underutilized by PI's.

Proven or promising external resources or approaches

No response

Response 1790

Perspectives on the postdoc roles and responsibilities

Since graduate school teaches you one set of biomedical protocols and techniques, postdoc should be a stage where you learn at least one other set of techniques used in biomedical sciences so that you don't become a "one-trick pony", so to speak.

Fundamental issues and challenges

Poor funding

High pressure

Lack of clear hiring process

The general sense of "have to get to megalab to get tenure-track"

Have to know the PI to get the position (but networking isn't a forte for many academics)

Existing NIH policies, programs, or resources

Clear hiring process

More centralised training grant processes

Proven or promising external resources or approaches

No response

Response 1791

Perspectives on the postdoc roles and responsibilities

In my view, the postdoctoral position is a time to bolster skills that were not required during graduate training. I see graduate training as a time to learn how to read and be critical of scientific publications, how to design experiments, think of how to get around pitfalls, and a time to learn to communicate your work effectively. As a postdoctoral researcher, it is now a time to learn how to manage multiple projects and execute experiments and write publications effectively. This is also a time to learn how to manage and run your own lab if this what you seek to do after your postdoc—managing lab teammates, networking

with others, being active at conferences, learning the financial responsibilities of running a lab such as grant writing and having someone be transparent with the costs of the lab. All of these skills could also be applied to working in an industry position, particularly the skills of teamwork and collaboration. Ideally, during this time, I believe the communication with the postdoctoral advisor should be more of a collegial partnership rather than a superior/subordinate relationship. Giving a postdoc the freedom to figure things out for themselves is essential for the growth of the postdoctoral trainee.

Fundamental issues and challenges

Inhibiting recruitment: I believe that this issue begins during the graduate training period. During this time a graduate student joins a laboratory where the graduate advisor plays a pivotal role framing the future of this student. If this relationship is strained, it will also strain the viewpoint of the graduate student on academia in general. The way a graduate advisor mentors a student during difficult times (such as grant rejections, paper rejections, failed hypothesis) is of utmost importance. If this experience is poor, so will the outlook of academia be for this particular student.

Retention: The inability to retain postdoctoral trainees is a multifaceted issue. First, many postdoctoral trainees are also at a time where they are forming families and the cost of growing a family is higher than ever. It is more appealing to begin making money in the workforce than delaying earning potential for a few more years. Secondly, visualizing a future in academia is exceptionally daunting. Science is becoming increasingly collaborative and team-oriented so first-author publications have become harder to publish. There are webinars describing how to apply for government grant funding but the acceptance rates are extremely low and application numbers seem to be increasing, making the overall outlook seem poor. Also, there is a lack of diverse role models in academia, people from differing, genders, ethnicities, and also from differing circumstances—someone who struggled to get where they were, who had poor mentors or a lack of publications but have still defied the odds and are great researchers.

Quality of life: I think this is highly dependent on your postdoctoral advisor. Some advisors have a very open mind and allow the postdoc freedom to have a work/life balance and others do not believe this at all, manufacturing urgency, inducing anxiety, or threatening termination of visas.

Existing NIH policies, programs, or resources

I think the NIH could offer more training for academic advisors to be better mentors for graduate students, fostering curiosity and optimism for a future in academia. It would be important to take generational attitudes of graduate students into account.

The salary could be reviewed for postdoctoral trainees, as costs are rising, postdoctoral trainees are at a pivotal time in life—starting families, or just being more competitive with other jobs that are available

I think that the mindset of the academic gatekeepers needs to shift to be more open minded in determining who a “good” academic is. For example, not everyone has an exceedingly high amount of first-author publications but is an exceptional scientist, curious about the world, and can still contribute greatly to academia. This should not intimidate nor hinder this individual from continuing their journey to be an academic researcher. Having diversity in advisors who look like and have experienced similar hardships to their students is essential for inspiring students to believe they have a place in academia

Proven or promising external resources or approaches

The T32 program seems to be a great program—having another advisor to advocate for your success.

Response 1792

Perspectives on the postdoc roles and responsibilities

Postdoctoral fellows are highly skilled and independent employees. They benefit their labs by bringing the conceptual and technical skills and perspectives from their PhD training, enabling them to rapidly start projects and work independently. In theory, postdocs acquire additional training, beyond what was available during their PhD, which enables them to start their own lab with fully independent projects.

Fundamental issues and challenges

1) Salary. Incentives for fair wages that recognize a postdoc's skillset, or at a minimum living wages, are nonexistent. Many universities use the NIH salary minimum as a maximum instead. Salaries do not keep pace with inflation. Housing and childcare costs have particularly outpaced salaries.
    a) Some universities punish trainees for winning fellowships. They reduce the trainee's salary to the value of the award, rather than continuing to pay them at previous levels. They cut their benefits, transferring them from status as a salaried trainee to an unpaid trainee. They put the full amount of their institutional allowance towards university expenses without informing the trainee.
    b) Employment contracts forbid trainees from taking second jobs, even as they can't afford to live on a postdoc salary.
2) Status as trainees. Postdocs are simultaneously students and employees, whichever is most convenient for the university to maximally deny benefits. Trainee status is used to deny childcare and retirement benefits granted to other employees their age. They often fill many PI roles on behalf of their advisors, writing the advisor's grants, mentoring the advisor's graduate and undergraduate students, and writing papers with minimal input from the advisor. PIs get credit for this effort and postdocs are, by definition of their employment contract, prevented from receiving credit.
3) Lack of training and mentorship. The lack of structure, as exists in PhD programs, creates low quality training. Moreover, a postdoc's quality of life and success in their field relies almost entirely on their advisor, a person whom they've only had one day of interviews to assess.
4) International postdocs. International postdocs are particularly vulnerable, as they often have no local support system when they arrive and can face deportation if they need to leave their lab. They are also unfairly unable to apply for most US-based funding mechanisms.

Existing NIH policies, programs, or resources

Restructure R mechanism grants to recognize mentorship:

Mentoring trainees is the main task of PIs, but R mechanism grants do not consider this element. Instead, the burden is placed on trainees, who must write training and mentorship plans for F and K mechanism grants. Mentor statements are in theory written by the mentors, but in practice are written by trainees. R mechanism grants could be scored on mentorship, just as F and K grants are, by requiring the following:

1) Evidence of experience mentoring the level of trainees funded by the grant as a component of the biosketch. Outcomes of former trainees, participation of the PI in diversity initiatives, and actions or training taken by the PI to improve lab culture and their mentorship abilities.
2) Plan for how the PI will mentor the funded trainees. How mentorship will evolve over the project as the trainee gains independence, the PI's specific role at each project stage, and what elements of the project they anticipate postdocs will be able to take with them to their own lab.
3) Including funded trainees as key personnel.
4) Increase and protect pay:
    1) Increase salary minimums. Salary minimums should be location-based to account for cost-of-living differences. The most effective way to accomplish this would be to increase the size of the modular budget by limiting the total funds or grants that can be held by a single lab. There are diminishing returns on each additional grant. The gender and racial gaps at the faculty level are exacerbated when examining recipients of multiple grants.
    2) Add language to fellowships (or require an institutional commitment letter) stating that, if funded, the university cannot reduce the trainee's salary, existing benefits must be maintained, and the institutional allowance should be reserved for research costs at the discretion of the trainee.

Proven or promising external resources or approaches

Re-imagine the postdoc as a staff scientist position:

Eliminating the postdoctoral role and replacing it with a restructured staff scientist role would be a boon for PhD holders and the labs that employ them. Such positions would be treated as employees in pay and benefits, improving recruitment and retention. Salary would be commensurate with experience, starting higher than current postdoctoral salary levels and with the opportunity to seek promotion. Staff scientists

could choose to remain in a lab, being promoted as they gain experience, thus offering a more viable option for scientists who wish to remain in academia without operating their own lab. These scientists would support the institutional knowledge of the lab and could act as the "vice-PI" . Such a role should also be accompanied by credit to recognize their independent contributions, including co-PI position on grant applications and corresponding authorship on papers.

Assemble a training resource library:

NIH could assemble a powerhouse training library for postdocs. Existing NIH training resources only scratch the surface of what postdocs need to learn. Rather than relying on each university to adequately train their postdocs, enable universities can share their existing workshops and courses nationally. Additionally, fund the creation of publicly accessible training academies, similar to Neuromatch Academy. Critical topics to incorporate include: grant writing, mentorship, teaching, applying for academic and non-academic jobs.

Additional recommendations:

1) Create a training resource about how to evaluate a postdoc lab environment before accepting an offer.
2) Return the K99 eligibility window to 5 or 6 years. This window punishes postdocs for taking risks, which may fail to produce results within the eligibility window.
3) Extend F fellowship eligibility to non-citizens.

Response 1793

Perspectives on the postdoc roles and responsibilities

I feel postdoc position gives the opportunities to explore the research idea more deeply and independently.

Fundamental issues and challenges

Postdocs are getting least salary compared to other job positions and work load, specially in academia. During this tenure we are always live in insecurity of sudden project funding discontinuation. Although after few years of postdoctoral research there is very low chance to get absorbed by academic positions.

Existing NIH policies, programs, or resources

NIH should increase postdoc salary and fund security to support postdoctoral training.

Proven or promising external resources or approaches

No response

Response 1794

Perspectives on the postdoc roles and responsibilities

For me postdocs should lead independent projects and help PIs to write grants and manuscripts for better career develpment. Postdocs also need to coordinate and coorporate with other coworkers to improve the social skills.

Fundamental issues and challenges

Low salary and job insecurity are the main problems right now for most of the postdocs. There's no good course for postdoc to learn how to write grants and there's also little opportunity for international postdocs to apply for grants. That makes it hard for international postdocs to get job security.

Existing NIH policies, programs, or resources

Make more courses and seminars about how to write and apply grants for postdocs, especially international postdocs. There's little information about how to write grants and what kind of grants is suitable for individual postdocs to apply.

Proven or promising external resources or approaches

Nothing

Response 1795

Perspectives on the postdoc roles and responsibilities

I view it as a role where I can independently do research—learn to form hypotheses and test them using the techniques available to me. It also helps me learn to manage time as I serve in multiple roles as an academic researcher. I also see myself as a team member who can brainstorm with a PI on their research ideas.

Fundamental issues and challenges

I don't know for sure. Lower payscale is a big factor for why postdocs tend to choose leave their research positions. Mentors may or may not be accountable to anyone for their role in training a postdoc.

Existing NIH policies, programs, or resources

Not sure.

Proven or promising external resources or approaches

None

Response 1796

Perspectives on the postdoc roles and responsibilities

As a PI I take the role of postdoc as a training period seriously. I make sure postdocs have independent projects and training opportunities and not burdened with administrative tasks or random research tasks. I learned this from my postdoc advisor.

Fundamental issues and challenges

For many, the PIs do not take the training and mentoring role seriously. Other than that, the pay and uncertainty are very difficult, especially if they have children or other dependents.

Existing NIH policies, programs, or resources

Higher stipend, ability to use T32/F32 institutional award for childcare, increased childcare allowance, instituting mandatory 12 week parental leave policies for T32/F32 and/or all NIH grants (I understand now it must be consistent with general institution policy), explicitly allowing expenses for partner travel/breastmilk shipping to NIH fellowships and grants

Proven or promising external resources or approaches

funding postdoc offices to support the postdoc community and training/development is helpful

Response 1797

Perspectives on the postdoc roles and responsibilities

The postdoc position is where scientists can gain various experience in broadening scientific vision, learning new techniques, supervising students, forming long-term collaboration, determining career path.

Fundamental issues and challenges

I'm an international postdoc. Therefore, my perspectives are more from the vulnerable group.

1) Visa issue—postdocs are particularly vulnerable because PIs can threat to terminate the visa and postdocs have to leave the country. This is extremely difficult for postdocs with a family.
2) Postdocs are invisible to the university. There are not built in mechanisms to support postdocs even at the department wide. Most postdocs are so restricted to the lab. If the lab is toxic, the postdocs life will be miserable.
3) PIs are toxic, selfish, and not helpful.
4) Many postdoc grants are only eligible for US citizens or permanent residents. This precludes international postdocs from low-income families.

Existing NIH policies, programs, or resources

Extend K99 eligibility from 4 years to 6 years.

Extend the diversity grants from US citizens to various visa holders.

Proven or promising external resources or approaches

Increase postdoc salary.

Response 1798

Perspectives on the postdoc roles and responsibilities

Postdoctoral trainees are a terrific source of enthusiasm and and bright ideas that challenge and invigorate my research program.

Fundamental issues and challenges

Few US-born trainees (and applicants) due to low salaries. Industry jobs have picked up in recent years, which has helped the pipeline. However, trainees perceive the NIH grant funding ladder has pretty bleak. The touted 20-25% success rate for grants = 75-80% failure rate.

Existing NIH policies, programs, or resources

Boost support to T32 and individual training grants. Put additional funds into K to R transition grants.

Proven or promising external resources or approaches

Need to train MD post-docs and PhD post-docs, preferably in the same programs. There are many opportunities in team science.

Response 1799

Perspectives on the postdoc roles and responsibilities

I think the postdoctoral position is an essential milestone for graduate students to move on to a higher position.

Fundamental issues and challenges

The career pathway is difficult to plan because it varies among disciplines, research topics, universities, funding opportunities, etc. Additionally, positions are very competitive.

Response 1800

Perspectives on the postdoc roles and responsibilities

Academic postdocs play an important role in training and mentoring graduate and undergraduate students, performing experiments and troubleshooting, running the lab/acting as lab managers, writing papers and grants. We’re highly skilled and capable scientists, but often feel overlooked and ignored by academic management. We’re exploited as cheap, disposable labor. Don’t like the low pay and working conditions? Then academia isn’t your passion, just quit and go to industry, there will be someone to replace you.

I love my research, I love my job, the people I work with are fantastic and my mentor is incredibly positive and supportive. But I constantly feel like I’m being pushed out of academia by a broken system—incompetent bureaucratic university management, financially exploitative conditions, few job openings beyond the postdoc stage in an academic setting (lack of permanent staff scientist/project scientist

positions), failure of university HR to discipline or remove faculty who engage in sexual and/or research misconduct.

Fundamental issues and challenges

The NIH minimum postdoc salary scale is a joke. It is insulting how low you think we should be paid based on how much experience, training, and expertise postdocs have. The minimum salary for Step 0 is below the poverty line for many high cost of living cities. Many postdocs who don't have generational wealth can't afford to take these positions. This is an equity issue—how can you recruit and retain individuals from diverse backgrounds when you're only enabling those with a financial support system to take these positions? As a postdoc I'm struggling more financially than I was as a grad student because I chose to take a position in a high cost of living city because it was the best opportunity for me. This significantly diminishes my quality of life. These struggles are even more severe for postdocs with dependents, especially since childcare support is basically nonexistent.

Existing NIH policies, programs, or resources

Would like more career support for postdocs that would like to be staff scientists (not aiming to become PIs or tenure track professor). The NIH should support and encourage more long-term, permanent staff scientist positions at universities, can could provide more grant support for these research faculty track positions. I don't feel like I qualify for many NIH postdoc fellowships because I'm not interested in a tenure track faculty position.

Supporting a Safe and Respectful Work Environment: You could hold toxic and abusive PIs accountable for their actions. Universities are clearly not willing or capable of enforcing positive work environments and are happy to protect the abuser if they continue to bring in big grants. Require universities to disclose allegations of misconduct (sexual, research, etc) to funding agencies and put them on probation from receiving grants if found guilty.

Proven or promising external resources or approaches

The problem isn't with scientific training or recruitment, it's the salary and benefits (or lack thereof). Even with the best of mentors and job satisfaction, we're underpaid and overworked compared to industry standards. Increase the salary scale, or require universities to give top ups. They're taking massive overhead off of PI grants, but that money isn't coming back to lab workers.

Response 1801

Perspectives on the postdoc roles and responsibilities

The postdoctoral position should be a place where one can receive further training on techniques that one has not yet learned It is presented as a step between graduate school and becoming a PI. Being a postdoc means that you have learned how to conduct solid scientific experiments, and that you now should be able to design and conduct your own experiments. It should be a place where you can openly discuss your career goals and your strategy to get there with your PI. Mentoring junior members of the lab should be part of this position, but you shouldn't be a substitute for the PI. Postdocs are a fundamentally important part of the lab because they can help to set up new techniques and protocols. Postdocs also bring a lot of new ideas to an existing lab

Fundamental issues and challenges

Many PIs treat postdocs like cheap labor who are there to advance the PI's career and they only care about your career goals in order to string you along. In a prior postdoc position I was treated as a lab tech and not allowed to do any of my own experiments, was just shoved in a corner to breed animals, ship packages, and manage the chaos of a lab where no one had any planning skills. Postdocs are supposed to show independent thought from their mentor and yet they are not allowed to envision or execute any of their own experiments, and are left doing pointless administrative work and training everyone in the lab for the PI. In reality postdocs don't get much time to do independent thinking or even to learn the things that they want to unless they work through the weekend. Especially depressing is that mentees of famous or established PIs are handed academic positions without even knowing what they are doing. Coming from a prestigious line of Ivy league schools or labs does not equal the ability to handle leading a lab. Many people with the right skills and personalities are sidelined or never make it there, especially those from minority groups. Pay is insulting for completing so many years of education and having specialized skills.

NIH and universities need to do a better job at making sure that PIs know how to mentor and lead a lab. Some of the tenured professors are the worst offenders and will verbally abuse you and micromanage every aspect of your time. If someone has a high rate of turnover, it is probably a bad environment and regardless of how much grant money they are able to get, they should be retrained to better handle personnel or fired.

Existing NIH policies, programs, or resources

It would be great to either be compensated better, and to expand programs in which student loans can be paid off without us having to pay tax on that as if it is income. I considered applying for the program where up to 50,000 of loans could be paid off per year; however I do not make enough money to realistically be able to afford the taxes on that. Making sure that F32s do not have such a strict time limit would also be a good improvement. I was in a terrible lab and missed out on that opportunity even though I was explicit when I interviewed that I wanted to apply for an F32. Postdocs also shouldn't have to have pay cuts for getting fellowship grants. There should be more training that is readily available to postdocs on subjects of interest that doesn't cost $3000+. Diversity initiatives need to be expanded. It is problematic that there are so few black PIs, and that they are less likely to receive funding. Something needs to be done about that. People with children often cannot afford daycare fees on a postdoc salary and that is not even taken into consideration. Universities should provide childcare as a benefit for employees and should build reasonably-sized, well-staffed daycares to accommodate this need. Payments should still have to be made, but it shouldn't be exhorbitant. It is unrealistic to tell women that they must wait until their 40s to have children and expect them to stay around. Universities shouldn't require you to relinquish the postdoc position after 3-4 years. It creates undue stress of moving and makes this career path inaccessible for many. NIH policies should change to reflect this. Postdocs should have moving expenses paid for.

Proven or promising external resources or approaches

Having a contract that the postdoc signs with a PI when they join that delineates more than just salary, but also a mentoring plan, funds for independent experiments, funds for attending training and conferences would drastically improve the position, especially if a neutral party evaluated this and made sure that all promises made were delivered. PIs that are reported to have a bad environment should have less of an ability to recruit postdocs. Paid moving expenses and child daycare are a must. Actually receiving mentoring and having regular meetings should also be included. More grants that postdocs can apply to as independent PIs would be ideal. These grants should not render postdocs ineligible for K99 if the funds are greater than $100,000 per year. It would be more satisfying to be able to get paid more for having such a sought after and specialized skill set. The low wages are one of the biggest reasons why postdocs are leaving academia in droves. That and the postdoctoral phase keeps getting longer and longer over time. Living paycheck to paycheck until your 40s is not something that most people are willing to do and it requires an exceptional amount of pre-existing privilege to do so. Universities should be required to match employees contribution to retirement fund and provide social security credits for all postdoc positions.

Response 1802

Perspectives on the postdoc roles and responsibilities

The academic postdoc is an intermediate temporary position meant to prove oneself as a scientist and to develop an independent research program. It is very fun to do research driven by one's own curiosity, and psychologically rewarding to make new discoveries. However, postdoc positions also come with a heavy psychological price (explained further below), so that every postdoc should try to move on as fast as possible.

Fundamental issues and challenges

To experience the quality of life, do thought experiment and maybe a real experiment, where you put yourself in the shoes of a postdoc in a high cost-of-living area. Imagine a role-play with the following set of rules:

1) Your role is a family of two adults with a child. Many postdocs are in their late 20s to early 30s, so this is realistic. Player 2 is not working and chooses to take care of the child (worth a $3000 monthly salary), or has no work permit yet due to their foreign visitor status.
2) Open a separate bank account and fund it with the typical postdoc salary as recommended by NIH ($ 56,484 / 12 months) or by several universities ($ 65,000 / 12 months).
3) From your role-play "salary", deduct health insurance ($700-$800 / month) and taxes (20%). This should leave a monthly $3150 (NIH) or $3700 (some universities).
4) Look for apartments in a high cost-of-living area such as Boston. For a family of three, one would ideally look for a 1-2 bedroom apartment and not a single room in shared housing. A 2-bedroom would cost about $3000 ([redacted for anonymity]) to $3300 ([redacted for anonymity]). While below market rate, this already blows the budget (point 3), so a 1 bedroom apartment as a minimum is more appropriate ($2400—$2700).
5) This leaves $450 (NIH) or $1000 (some universities). Using these funds, the goal of the role-play is to survive for 2-3 months.

Ultimately, one has net negative cashflow and consumes their savings. Since salaries reflect the worth of an individual in the eyes of an employer, the message set by NIH seems clear: postdocs are worthless work slaves and are not supposed to live like human beings. This leads to self-doubt and sleepless nights, which ultimately also impact productivity and stint the research enterprise.

Existing NIH policies, programs, or resources

1) Possible sustainable solutions:
    a) Pay a subsistence wage that accounts for the local cost of living or
    b) At least provide affordable housing that is not inflated by the 2-5x larger salaries in biotech. A tool that you could use: https://livingwage.mit.edu. Further sources: https://www.nature.com/articles/d41586-023-00332-6, https://arxiv.org/abs/2205.12892, https://www.nature.com/articles/d41586-020-03191-7, https://www.nature.com/articles/d41586-022-02781-x.
2) One small step forward would be to educate faculty about inflation and equity. Many seem to still live in the 80s, with a corrupted mindset that they weren't rich either so the current generation should not have it any better. Stop criticizing postdocs and the young generation. It is not greedy to try and simply survive paycheck to paycheck.
3) Visas/work permits for longer than a year would be great.
4) If you are looking for small band-aids, then you could create a program that educates postdocs about cashback credit cards. Some faculty try to "solve" the survivability problem by suggesting that postdocs and graduate students apply for subsidized housing and food. Some faculty suggest that one should think twice before marrying and getting children. To make the point obvious: This suggestion is preposterous and stupid. Moreover, the second "strategy" is a burden on the taxpayer and creates problems with the stipulations of many visa types. Yet the current salaries already violate visa stipulations if they are not sufficient to pay for the cost-of-living, so maybe you do not even care. Given that instead of making cost-of-living adjustments you would rather waste taxpayer money for even more bureaucracy overhead (more than 50% of the salary already at some universities), advisor fees, program costs, and resources that have no use other than waste time, my bet is on the latter. Small hint: at least I, and postdocs that have not lost their mojo, like to spend time actually working and not doing useless stuff.

Response 1803

Perspectives on the postdoc roles and responsibilities

The postdoc position is a training position that should facilitate the transition between a graduating PhD student and whatever comes next—tenure track faculty, senior position in industry, etc.

Fundamental issues and challenges

I believe in the past the training part of the postdoc was viewed by many (including myself at the time) as an investment in my future. I was willing to accept lower pay in exchange for better job prospects as a tenure track faculty candidate, which worked out as advertised for me. One issue that I see is that the pay-off at the end of the postdoc has become devalued—good faculty jobs are harder to get and many faculty seem unhappy in their positions. This makes the deal harder for postdocs to accept—should they invest a few years of lower pay for a possible shot at a job they might not get, and that people who have it are often unhappy with? When this combines with the emergence of other better alternatives it's a hard choice to make to stick with the postdoc system.

Existing NIH policies, programs, or resources

Everyone would like postdocs to be paid more, so that the "investment in your future" I described above is not such an extreme ask. Asking someone to sacrifice 5 years of $50K lower wages than they would obtain elsewhere is huge investment, especially if there's a chance they will emerge with a job they could have gotten right out of their PhD. So I think higher pay would help lower this "investment" cost. Also finding ways to deliver value to the postdoc beyond the big payoff at the end if they are fortunate enough to get their dream job (ie: adding more explicit training).

In terms of NIH policies, I think one main tension resides in the fact that many postdocs are paid from research grants, and not training grants. But the postdoc position is a mix of research and training. So many postdocs are hired to complete research goals of a grant, which the faculty needs accomplished for their own careers, grant renewals, etc. But this can conflict with training and career development goals of the postdoc, which creates a tension where the postdoc feels like they are being treated as an under-paid employee of the lab, while the faculty feels like the postdoc is focusing on too many training or career development activities that are not what they were hired to do. I'd like NIH to find a way to clarify the balance of training vs. work on research grants that postdocs are expected to engage in, which might require increasing the budget for fellowships and training grants so it's clear what effort a postdoc should spend on working on funded research projects vs. training for their own future careers.

Proven or promising external resources or approaches

Sorry I don't know anything proven here.

Response 1804

Perspectives on the postdoc roles and responsibilities

Academic postdoc was a great experience for me to expand my knowledge scope, improve my critical thinking and independent research, and learn how to collaborate for the purpose of my study.

Fundamental issues and challenges

The discrepancy of the salary with getting an industry job after graduate school study and that with being a postdoc is huge. Many PhD students may choose to go to industry in stead of becoming a postdoc.

The other reason might be the funding limit that some labs face. PI needs more funding to support a postdoc's salary and research activity. Even more importantly, when a postdoc needs to become an independent PI and look for academic jobs, the PI still can support him/her even he/she has lower working load in the lab.

Existing NIH policies, programs, or resources

Increase funding to academic labs and more importantly to young PIs.

Proven or promising external resources or approaches

Increase funding used for training of postdocs, including postdoc fellowships, postdoc career development, postdoc skill trainings, and postdoc working environment.

Response 1805

Perspectives on the postdoc roles and responsibilities

My view of a postdoctoral scientist is laid upon a hierarchy in a traditional laboratory dynamic. They're on nearly equivalent playing field's as their researching P.I. may be, but haven't crossed the great divide that profoundly separates the responsibilities involved in the latter role's position related to the overall dynamic of a research lab.

Fundamental issues and challenges

Tuition reimbursement benefits as a more, immediately accessible—even if that's to limit it's activation to begin at the end of one's hiring company's "probationary period. For WashU., this is 9mnths after one's starting date. A generalized list of suggestionsto improve are as follows: The general lack of active recruitment is prevalent throughout academia. The little that does happen is constricted by H.R. "standard's," which are listed in the job outline of any particular role. Evaluations are based only off of a candidate's professional paper trail.They should reflect an individual's overall background, what they've done in their absence from academia (wherever/whenever this question would be applicable)??? Why do you want to return to science (a whole new world of present day's laboratory standards) for a candidatelike me, such as: how we tend to use a mechanized approach to image gels nowadays. Instead of how I was trained to use a light-board and some simple software programs. We've made the processes safer for the involved researchers, but in doing so, we've added another hurdle for a candidate like me to jump over in my re-entry to what makes me feel challenged in a stimulating environment. Ultimately gifting me with the necessary challenges to derive greater purpose in being gifted the opportunity to be part of something much greater than my own ambition. Ensuring candidates meet a one size fits all model of requirements doesn't allow for innovative thinking by people's w/o said requirements, but could easily be brought up to speed within the first 2-5 month's of beginning work in a new laboratory. Who's willing to invest the time is the nitty-gritty question? Or would the university extend initiatives for outreach programs to accomplish similar goal's in order to enhance their workforce and increase their overall abilities???

Existing NIH policies, programs, or resources

Their initial investment of taking a chance outside of the listed requirements will come full-circle, so that I'll meet the requirements put forth by higher administration's than the hiring lab-P.I., but allowing them the leeway to take a calculated chance on applicants who may not already meet the required qualifications for a specific job opening, B/C it's not helping anyone but the hiring parties involved. Extend educational incentives, initiatives for community out-reach, centralize a hub so that the proverbial left hand talks to it's counterpart; and ensures nothing is lost in translation betwixt H.R. and hiring managers.The practice of being exclusive doesn't breed a creative, critical problem solving set of skills as a researcher. What it does do is cause a divide in status equality amongst a lab's member's. Undermining the fact that each role's a necessary one and shouldn't be valued more or less than another. The only time the traditional hierarchy should be a tool we use, is during disciplinary actions we're obligated to report and/or enforce if the problem and/or actions necessary are within our control. Otherwise, appropriate applause should be given more often and providing constructive criticisms to applicants who a hiring manager's moved beyond, is only professionalism at it's finest. Practicing it with promising scientists who can't meet requirements yet, means alot more than it may be thought of as, because it assures the applicants expert advice to improve if they're choosing to move forward and letting nothing stop them from achieving their goal's. Scientific enrichment isn't only for the workplace. Alot of it happens outside of one's workplace.

Proven or promising external resources or approaches

I'd normally recommend specific talent acquisition company's like Randstand Scientific, but have seen how often these services can misrepresent or cause additional issues during a hiring process. And more often than not, they're not equipped to handle interviewing laboratory researchers on any level. The only way I can perceive it done with justice is to implement "working interviews." If a hiring manager is looking to fulfill a specific role and a candidate passes pre-screening with an invitation into lab, show them where

essential reagents are kept, utilize a set of data that's already been logged, and have them run through the process in front of the interviewing party -starting and stopping at any points the hiring team requests, so nothing's used/wasted that's not expendable. The correct data is already present and logged for the hiring manager's review and feedback at the end of an interviewing process. Invite them into a conversation rather than an interviewing questionnaire, if/once they've reached this point. Finalize by doing a secondary re-evaluation, after seeing hiring candidates go to work in front of you, to provide the best feedback for real progress to be made in the future. It'll also be a more comprehensive interviewing technique for prospective new-hires.

Response 1806

Perspectives on the postdoc roles and responsibilities

The position is in part training and in part independent. The balance of these two components, and the nature of the 'training', varies over time. The quality of the 'training' is also varied and dependent on the mentor. To me, the postdoc position is meant to learn the skills for the desired next career step. These skills included independently leading research, including starting and finishing a project, mentoring, written and oral communication skills, budgeting.

Fundamental issues and challenges

1. Salary and job uncertainty. Why would I accept lower pay than I know I can get in industry (or consulting or data science or whatever) to gamble on landing an independent academic position? Especially when this academic position comes with the permanent stress of funding.
2. Lack of benefits and retirement. Between graduate school and postdoc, I have missed out on an employer match for retirement for >12 years, at the point where these dollars have the most time to grow.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1807

Perspectives on the postdoc roles and responsibilities

A postdoctoral position should be a period of time in which a recent PhD graduate learns to start their own, independent research program. Postdocs should no longer be considered trainees, but rather scientists transition to independence. It should be viewed as a protected period of time during which a scientist can develop their research plans and apply for early stage funding mechanisms that will foster their transition to faculty.

Fundamental issues and challenges

The largest issue is financial. Asking individuals who just endured 5-7 years of underpaid and undervalued work as a PhD student to continue that work is challenging, particularly when these people tend to be in the stage of life where they might want to start a family and establish "roots". Beyond just low stipend pay, you are asking postdocs to give up many benefits that a person working in industry has had for the last 5-7 years—eg. 401k, other retirement savings, insurance benefits, etc. Now not only are postdocs being paid less each month, but the longer they stay in this academic position, the worse off their retirement outlook is. In today's current climate that is just too much to ask of a lot of people. This culture of treating postdocs like trainees is also disheartening. I don't feel like a valued member of my research community because of the benefits that were taken away from me when I became an NIH sponsored postdoc (T32 program).

Existing NIH policies, programs, or resources

I don't think the NIH is doing enough to protect postdocs from being taken advantage of. There should be stricter limits on postdoc length and increased stipends. While the stipend levels may just be a guide for

what universities can pay (the NIH itself pays above these levels, likely because they know its not a livable, competitive wage), every university I know uses these as an excuse to underpay their postdocs. Listing stipend ranges up to 7 years encourages unnecessarily long postdocs. We also need to increase benefits available. As a graduate student, the money in my F31 NRSA budget which was supposed to pay for my health insurance was actually taken by my university, so I continued to pay insurance out of pocket. We need to ensure the funds granted by the NIH are being used properly. In addition to money for insurance, I think the NIH should set guidelines on allowing postdoctoral fellows the ability to save for retirement. If we are not eligible through university retirement plans because institutions claim we are employees of the NIH when on fellowship, there should be an option for NIH retirement plans.

Proven or promising external resources or approaches

I believe the most progressive and competitive postdoc program available comes from St. Jude (https://www.stjude.org/education-training/advanced-training/postdoctoral-fellows/funding-benefits-for-postdocs.html). Beyond a substantial stipend increase, they offer sign on bonus, paid leave, insurance benefits, retirement plans, and relocation assistance. These benefits would go a long way in helping ease the transition to postdoc and retaining researchers.

There are also several universities offering postdocs with transition tracks to faculty. This would help alleviate some job insecurity. If NIH fellowships came with some guarantee of transitioning to faculty or at least assistance in finding faculty positions. Right now we are left up to our own to research, earn grant funding, and find a faculty position at the same time.

Response 1808

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

No response

Existing NIH policies, programs, or resources

I believe support mechanisms should exist at the institutional level for an undergraduate university to house a diversified post-doctoral work force whose purpose is to bridge the gap between RO1 institutions and research and R15 institutions. Undergraduate universities have too transient of a work force to make significant contributions to the knowledge able given the emerging pace of new knowledge and service and teaching loads most faculty face. A dual mentorship between a RO1 faculty member and a R15 department with a dedicated R15 faculty mentor, would allow for development of early career individuals in a more supported setting. Typically the transition from post doc to early faculty member at an R15 institution is too abrupt. Often they don’t know what the expectations and capacity is really like. This would allow them to perhaps teach a single course, while truly establishing their project in a new space, and still maintaining ties with a larger institution where resources are likely more plentiful.

Response 1812

Perspectives on the postdoc roles and responsibilities

Extra training and/or multi-disciplinary/interdisciplinary training and a good transition between being a graduate student and becoming an independent faculty member; the ability to apply and practice the foundational knowledge obtained in graduate school to the research process and gain experience seeing how research projects work from start to finish; an opportunity to focus all or most effort to research, including an opportunity/time to get manuscripts published which can increase your competitiveness on the academic job market; professional development.

Fundamental issues and challenges

First and foremost—the pay. Postdoctorates are EXTREMELY underpaid and most postdoc salaries (even those not funded by federal or governmental funds/grants) use the NIH Fellowship and Training Stipend Levels to set salaries. This creates a major source of inequity in training. If I was single (i.e., not married) and did not have a multi-income household, I do not believe I could financially support myself on a postdoc annual salary, and I live somewhere that would be considered a lower cost of living (i.e., not Los Angeles, New York, San Francisco, etc.). Why would someone take a drastically lower pay as a postdoc if they could be receiving the salary of a junior faculty member, even if completing extra training as a postdoc would ultimately help them in their career? Furthermore, unless a postdoc is in a T32 program or on an F32 or something, they get basically no research funds of their own or stipends to travel to conferences, publish in open-access journals, etc. Postdoc pay should be similar to or only slightly below that of a junior faculty member (not $25,000-$50,000/year lower). Second, postdocs are often asked to

basically manage entire projects on their own (sometimes more than one at a time) with only a little supervision or necessary input by PIs, and therefore creates an unrealistic and overwhelming workload, especially for such little pay. I believe these issues can contribute to some serious mental health challenges for trainees. In my opinion, these are the two largest issues impacting the recruitment, retention, and overall quality of life of postdoctoral trainees.

Existing NIH policies, programs, or resources

First, please raise NIH Fellowship and Training Stipend Levels to a liveable and fair wage for trainees. Second, make the review process much shorter for those applying for training grants (e.g., F32, K99/R00). Because several, if not most, trainees applying for training grants are already in some type of trainee/postdoc position (i.e., temporary positions), it is completely unrealistic to have a 9 to 18-month turnaround time for training grant funding. For training grant resubmissions especially, there needs to be a quicker turnaround. Most people are only guaranteed postdoc funding for 2 or possibly 3 years, especially those in behavioral and social sciences, so an 18-month timeline for funding (assuming a resubmission is needed first) would mean that a postdoc would have had to submit a training grant within the first 6 months of their new position—that means 6 months to put the entire grant together, including the training and research sections, on top of acclimating to a new job and possibly new institution or department. It doesn't make sense that training grants should be on the same timeline as much larger grants. It's not realistic.

Proven or promising external resources or approaches

pay increase, quicker turnaround time for career development awards or training awards, and possibly requiring some type of training for PIs overseeing a postdoc to understand workload, role distinctions, equity, mentorship, etc.

Response 1813

Perspectives on the postdoc roles and responsibilities

Postdocs are the workhorses of the lab in my field (neuroscience). We have the tools necessary to run projects independently and our training mostly focuses on learning how to run projects, manage personnel, and write more advanced grants (along with maybe picking up one or two more techniques). We are supposed to blend our past experience with our current lab's culture and procedures to both drive projects forward and teach more junior lab members new techniques and expertise. The roles of postdocs are very diverse and lab dependent but it seems like we get saddled with a lot of the heavy lifting in whatever our areas of expertise are.

Fundamental issues and challenges

It seems like the overarching guiding principle of academia is that if you want it bad enough, you'll put up with anything. But the raise of industry alternatives combined with the relatively low success rate of landing a tenured position and generational shifts in attitudes towards work-life balance make it really hard to stay motivated to continue on career paths in academia.

It has also been my experience that many PIs are extremely ill-equipped to manage teams of scientists and universities do not take trainee complaints seriously. It's wild to me that senior people know their colleagues are terrible to their trainees and have track records of being miserable advisors and yet there aren't more serious attempts to correct their behavior.

What is the incentive to stay in this system if my future job prospects within academia are bad, my pay is garbage relative to people of my age and skill set, and PIs are often allowed to treat us however they please with impunity? I love my work more than almost anything and do not want to leave academia but I am not going to stick around in the current environment.

Existing NIH policies, programs, or resources

There are some great programs like the T32 training grants that provide opportunities to have larger advisory groups and distribute the power dynamics governing a trainee's life to many professors rather than one. However, the issues are far to systemic for simply expanding existing programs. Pay may have kept up with cost of living generally (at least for postdocs) but it has not kept up with our actual workload or to pay outside of academia.

Programs have popped up to promote equity but power dynamics remain extremely imbalanced. It is great that science is diversifying from a bunch of old white dudes running everything but there's clearly massive conflict between old school and young scientists that is not being resolved.

The best thing the NIH can do at this point, in my opinion, is support/allow/not resist the unionization of graduate students and postdocs to allow us to directly advocate for ourselves because our institutions failed for too long. Alternatively/in combination increasing funding for trainee salaries generally would be a huge help for retention. Lastly, increasing the availability of non-Associate Professor positions (i.e., staff scientists, research professors) via funding would provide some hope for alternative careers within academia.

Proven or promising external resources or approaches

Unions

Response 1814

Perspectives on the postdoc roles and responsibilities

The academic postdoc is akin to an indentured servant.

Fundamental issues and challenges

Although I was successful in publishing and people management during my PhD experience, I found my postdoc experiences to be miserable and unproductive. The postdoc position puts young people who are vulnerable financially and in their careers in a dangerous position. The role carries with is an intrinsic unfair power dynamic between the post doc and the PI. While it appears that the PI needs to treat the postdoc fairly in order to publish, in reality it turns into a stick-and-carrot scenario and there are no repercussions for the PI. I personally was reprimanded by my PI for going to an ombudsman at my state institution and during an interview at another flagship state U I was asked if I was married and told that I would be more likely to get the position if I did not have any dependents for health insurance. At the time, my family was being threatened and retained a restraining order; when my PI noticed I was upset they told me to leave those feelings at home, instead of giving support or suggesting I take time off. I was denied a meeting with HR for about a month while my PI gathered information against me on my personal computer. I was not given either the learning opportunities I had been promised nor the equipment and tools I needed to work. There was no recourse for me, when I was strong-armed into quitting. Being a post doc, NOT a PhD student, was the worst period of my life in terms of mental and physical health to the point where other adults not in the field could not believe how things were being run.

Existing NIH policies, programs, or resources

Post docs should be in charge of the funds that they are paid out of and which their research budget comes from. There needs to be more transparency. PIs need to be held responsible and need EXTRA HR training as many of them think that their positions exempts them from making racist statements, making sexual advances on students, and demanding long hours without weekend breaks.

There are no sick days given for post docs or sick day guidelines. There are no vacation days nor vacation guidelines. Post docs fall through the cracks in the worst possible way. Those who survive are jaded and want to punish those who come after them; those who do not have no savings and are OVER qualified for many non-academic jobs.

Proven or promising external resources or approaches

Institutions should keep track of post doc job satisfaction and should be required to make that data public. PIs should be made to take training on how to manage people and how to manage funds. There need to be rules in place so that post docs are not punished for "taking time away from work" to go to things like job skills seminars.

Response 1815

Perspectives on the postdoc roles and responsibilities

Gain valuable experience into the role of research, both specific to the field of study (biology, physics, etc) and with the role of science and research in society and institutions as a whole

Fundamental issues and challenges

Number one reason is funding and compensation. I earn more money as an industry clinical scientist right out of undergrad than someone with a PhD and years in a post doc.

Appreciation and general perspective of post doc scholars. The expectations and traditions of academia are not compatible with a young, driven, and knowledgeable group of future scientists who know how to be treated and appreciation. In other words, potential post doctoral scholars are going into areas where they are respected and appreciated, and many traditional post doc environments do not fit the bill.

Existing NIH policies, programs, or resources

More centralized and modern training by NIH on how to leverage resources to better support post docs, and training on how future post docs want to be treated and what role they will play in contemporary research science

Proven or promising external resources or approaches

See above, and encouraging appreciation and understanding of the post doc role for all individuals in a research lab setting

Also working with potential industry partners to create "post doc to career"pipelines that allow academia like training with industry compensation

—[redacted for anonymity]

Response 1816

Perspectives on the postdoc roles and responsibilities

When I started it was more to gain experience and extend my academic abilities to be a future researcher or an academician. But after four years, it feels like an academic cage where with no external and internal solid support. My career is depending on PI mercy even for the justified academic credit and salary way lesser than the NIH scale (no questions).

I personally feel, authorities should be more vigilant on postdoctoral fellow progress. We have IPD however, no one wants to fill it. Even if you filled it out, no one has time to look at your goal.

What changes do I feel that should be incorporated into postdoctoral training—

1. Review committee for IDPs
2. Drop box facilities for postdocs where they can put their complaint.
3. Timely review of salaries.
4. Other facilities.

Fundamental issues and challenges

It is very well known that the quality of postdocs' life is not so good. I started my postdoc carrier in late 2018 with defined goals and ambitions. However, after four years, specifically, after the pandemic things have changed a lot. There is a lot of pressure from the academic and personal front, which is not compensated by fellowships. As fellowships are not getting raised, it is still the same amount as earlier. Even the living cost becomes double.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1817

Perspectives on the postdoc roles and responsibilities

Postdoc should last a few years after obtaining a PhD and then moving on to the next job. Try to as much quality research as you can, but also enjoy life, build a family.

Fundamental issues and challenges

They pay is very low, the hours expected from a typical postdoc are long, and most are expected to come in the weekend. Limited vacation days (general US problem) and if you are sick you feel guilty for staying home. Why would people continue to pursue a postdoc when they can work in industry for set amount of hours and make more money?

Postdocs just came out of PhD in which they had to work a lot, now it is time to work regular hours I think and start a family. Or, if you are child free like me, just enjoy your life while you can and you are still young!

Work to live, not live to work. However, because most of the PIs are so very old, and they used to work hard during their postdocs and ignored family they expect the same from you and it gets propagated.

It is a very unhealthy system.

Existing NIH policies, programs, or resources

Improve pay, make it equal across the NIH institutes, NICHD alway pays postdoc the bare minimum and minimum increase.

Increase vacation days for postdocs and visiting fellows and give them sick days.

Institute and communicate that coming in in the weekends should not be the norm

Proven or promising external resources or approaches

No response

Response 1818

Perspectives on the postdoc roles and responsibilities

I love being a postdoctoral researcher and I love academia. Being a postdoc provides us with the intellection freedom to explore important and interesting scientific questions, learn from the previous generation of scientists, and advance human knowledge.

Fundamental issues and challenges

In cities with high cost of living and rising inflation, the NIH minimum for postdoctoral salaries is not nearly enough. This is a huge problem for retention, with more and more individuals opting for private industries instead of academic career paths. Childcare in Boston alone is around $50k per year, creating a barrier for women seeking to pursue careers in research. This is a huge problem for retention of postdocs. In the long term, I worry quality of academic research in this country will suffer tremendously.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1819

Perspectives on the postdoc roles and responsibilities

It is a period in which the professional will develop new skill sets if working in a different area from grad school, as well as a period to improve communication, mentorship, leadership and teaching skill, besides understanding how to navigate the grant cycles if staying in academia, or to develop necessary skill to prepare the individual to launch an industry job or a startup company and so on.

Fundamental issues and challenges

It is hard to navigate the system alone as an international postdoctoral, since usually local academic researchers don't know about opportunities international postdoctoral scholar can use to advance their own research careers. Usually, the majority of opportunities are restricted to US citizens, and we are not allowed to participate in specific training programs that would allow us to be independent researchers in a near future. Basically, we are left behind.

Existing NIH policies, programs, or resources

One of the main modifications could be implementing online courses in platforms as Edx to be offered to every student for skills development as leadership, communication, grant writing, project management, statistics, as well specific courses directed for students that would like to prepare themselves to become a future PI, as mentorship, laboratory management, student recruitment. This set of courses could be offered to every student, independent of their background, US citizen or non-US citizen. This type of program would benefit students that would like to stay in academia or leave it, since they are basic skills for jobs outside academia as well. They could be offered in a package for everyone, graduate students and postdoctoral trainees at no cost or with a small cost.

Proven or promising external resources or approaches

The PALS program Succeeding as a postdoc it is interesting, since it helps postdoctoral scholars to build a community around them to improve their educational experience. Another programs for minorities recruitment that were launched in some universities as Cornell, are also interesting if everyone is included, independent of being citizen or not. The postdoctoral need close mentorship to transition successfully, besides a salary that really cover their life costs, and not only a research project to produce papers. For an independent path, they need to be aware of opportunities, and allowed to take the opportunities. A guide with opportunities for both, academic scholars that are citizens and non-citizens, should be compile at NIH and should be distributed by every university to improve experience to everyone, with contents as their rights, obligations, where to go for help if problems with PI appear, as being aware of the human resources department, NIH grant workshops, how the grant cycles work, opportunities of fellowships for everyone, when to start applying, opportunities of leadership or courses offered by NIH, general guidelines of whom could apply for recurrent opportunities. It does not take a lot of effort to do it, and the benefits will be immense for both, graduate students and postdoctoral. We really need guidance, and we usually don't receive it. That's why the majority prefers industry, easy to navigate, clear paths and rules, instead of a black box created by academia. A 10-30min of mentorship per week as modus operant in the majority of the laboratories will never fix the problem, and students will be always frustrated about their experience. We really expect more in our overall experience, and our expectations are high for an agency so well-known through the world, besides the American universities training experience.

Response 1820

Perspectives on the postdoc roles and responsibilities

A critical part of the research workforce. Invaluable to research projects

Fundamental issues and challenges

Hard to entice postdocs to the lab when a. the pay is so low that they do not want to move to a big expensive city and b. if they do move, the biotech companies close by can pay way more and they lure the postdocs away. Pay and benefits and potentially other perks need to come a long with being a postdoc.

Existing NIH policies, programs, or resources

NIH stipends should not be equal across the board—more expensive places to live should get a higher living wage. Access to more federal programs that all postdocs can access—training, career development, etc. that are not dependent on different institutions.

Proven or promising external resources or approaches

No response

Response 1821

Perspectives on the postdoc roles and responsibilities

The postdoctoral position, to me, is a training position and opportunity to explore career options. While a postdoc is technically a training position, postdocs have many roles and responsibilities in the lab and university that are more similar to faculty responsibilities. Postdocs are often the main mentors in labs and often help with all of the students and projects in the lab. They also often have teaching responsibilities. So, while the postdoc is called a training position, the responsibilities and expectations often exceed that title.

Fundamental issues and challenges

The main issues I see with recruitment, retention, and overall quality of the lives of academic postdocs is low pay and lack of information and respect regarding the status of the role. We are somewhere between faculty and employee, but pay and benefits do not reflect this. And the lack of information on the role of the postdoc (institution-wise) causes postdocs to fall between the cracks and go unnoticed. For example, at my current university the entire provost's office and research affairs were unaware of any issues brought up by postdocs. We had to have a direct meeting with them, and many canceled last minute, making it seem like postdocs are not a priority outside of the research departments. It is exactly the opposite. Postdocs generate most of the data that goes into grant applications, such as R01s, that directly impact the university. The majority of labs would NOT function without postdocs.

Most postdocs end up going into industry, where there is significantly higher pay, a path to a career, and better treatment which stems partly from defined roles and expectations, which would alleviate mistreatment and overworking of some postdocs. It is obvious to see why so many postdocs are leaving academia.

Existing NIH policies, programs, or resources

The main and obvious change that could be made is higher pay.

Proven or promising external resources or approaches

It would be important to look at where all of the postdocs are going, and what they are choosing over academia. Look at industry and biotech postdoc positions and try to make an academic position look more reasonable.

Response 1822

Perspectives on the postdoc roles and responsibilities

To learn about new research directions or skills you did not have the opportunity to explore during your PhD or only learned about during your PhD. To gain additional experience before launching an independent career

Fundamental issues and challenges

The postdoc salary is too low, especially in high-cost-of-living cities. Postdocs cannot apply to independent funding mechanisms only mentored positions

Existing NIH policies, programs, or resources

Modify the payscales and increase the number of grants postdocs can apply to

Proven or promising external resources or approaches

Improving postdoc pay

Response 1823

Perspectives on the postdoc roles and responsibilities

The role of a postdoctoral scholar is to supplement their PhD training to propel them into successful research and teaching career. With respect to research, their responsibilities should include engagement in development of research questions, research studies, forming of clear hypotheses and expanding on data

management/quantitative analytic skills. With respect to teaching, their responsibilities include mentorship and management of scholars and dissemination of their knowledge in the form of developmental and conference presentations and publications.

Fundamental issues and challenges

First and foremost, financial. I received a postdoctoral fellowship that

a) does not meet cost-of-living in the area where the university is located,

b) my university does not cover my insurance and so all $11,950.00 of my institutional allowance that was budgeted for publication cost, research travel, equipment has gone to my university insurance payments and

c) the merit raises are no existent and is demoralizing as the starting salary is equivalent to a the salary of research coordinator which I was one minus 8 years of experience.

Second, devaluation of postdoctoral scholars. For every university that I have talked to postdoctoral scholars (five in total, three of which are top-10 universities) all agree that the departments value graduate students more than postdoctoral researchers. While labs can respect and value postdoctoral scholars, the universities do not show an investment to care.

Third, limited job prospects. Multiple senior faculty have agreed that postdoctoral positions have turned into 'holding patterns' and the no longer serve the purpose that they did: funding and experience bridge to faculty positions. Universities are simply graduating too many PhDs and universities have far fewer openings. Then, faculty are simply not incentivized to retire which further creates a generational backlog.

Fourth, I am a first generation immigrant, first generation college student, received free lunch during K-12 and grew up in low-SES neighborhoods. This type of background is underrepresented in academic circles and so it is quite difficult to relate to people that have the resources and support.

Existing NIH policies, programs, or resources

NIH has a disadvantage/underrepresented program in place but it remains to be seen how much this will improve things. It throws money (which see above, 53k/yr stipend) at a problem and tells the universities and/or labs "Here, help these students succeed". What if the universities and/labs are not set up to facilitate this?

Proven or promising external resources or approaches

No response

Response 1824

Perspectives on the postdoc roles and responsibilities

It is a job. I conduct research with input on the overall goal from my mentor but I decide on the experimental approach and data interpretation. Mentoring undergraduates and graduate students in the lab is another large part of my role. I also contribute significantly to preparing figures for and writing grants. I see myself as a senior scientist in the lab. This is a time for me to acquire new skills, build my curriculum vitae with more publications, and begin formulating what my own independent lab will eventually work on.

Fundamental issues and challenges

Salary and career prospects are the major deterrents to doing a postdoc. My peers in industry jobs make two to three times my salary without the pressures of academic science. Knowing that only the top ~10% of scientists get the majority of the opportunities (i.e. tenure track faculty positions and grants) combined with low pay and the impermanence of a postdoc position render this job unappealing. Financially, it is very difficult to make living in a city work, especially if you have a family, without a great deal of privilege like a high income spouse or support from family. With all of these challenges, unless you have a near-perfect relationship with your mentor and a healthy lab environment, staying in a postdoc is just not worth it. Many of my peers have abandoned academic ambitions because they cannot afford to live and/or experience unhealthy toxic work environments.

Existing NIH policies, programs, or resources

Higher salaries for fellows. Especially the F32 since this is the pay scale most universities adhere to. Adding benefits like retirement, paid maternity leave, ect for fellows would also go a long way. We often have to choose between what is good for our careers and what is good for our lives/families when considering an NIH fellowship.

Proven or promising external resources or approaches

No response

Response 1825

Perspectives on the postdoc roles and responsibilities

I completed postdoctoral research training in the setting of medical fellowship training. I am MD-PhD trained, did a pediatrics residency, and then did fellowship where 2 years of my 3 year fellowship were spent doing research. This research period was critical to my success as a physician scientist with K08 and R01 funding.

Fundamental issues and challenges

Within my niche area of pediatric infectious diseases, the number of fellows pursuing basic and translational research during fellowship is decreasing. Oftentimes fellowship has to be extended by a year in order to allow additional protected research time before a person can get a K award and be hired as a physician scientist with a start up package needed to support a research lab. Our specialty is the lowest paid medical specialty, and we are paid less than general pediatricians who do not do fellowship, so there is a financial disincentive to both complete peds ID fellowship and extend fellowship by a year to get a K award.

Existing NIH policies, programs, or resources

The loan repayment program is really important for time. The period between the end of fellowship and when a person is awarded a K award is a huge cliff where people leave academic research—a program that offers salary support for this year with 75% protected time would be really helpful. Increasing the number of K12 grants awarded to institutions would help.

Proven or promising external resources or approaches

No response

Response 1826

Perspectives on the postdoc roles and responsibilities

A Postdoctoral Scientist has the responsibility to plan and conduct experiments, train students and technicians, write projects proposals and scientific articles, while learning how to lead a group and obtain funding to become an independent researcher.

Fundamental issues and challenges

Salary and difficulties to achieve work/personal life balance. Is a role that requires more time commitment than others, with a lower salary. Is also stressful for foreign Postdocs that don’t have many funding opportunities which will also limit their chances to get a Faculty position.

Existing NIH policies, programs, or resources

Include more funding opportunities for foreign Postdoctoral scientists and support for career transition. It would be very helpful to have proper orientation and financial support for immigration/visa procedures.

Proven or promising external resources or approaches

No response

Response 1827

Perspectives on the postdoc roles and responsibilities

Post doc training means a lot to me , early investigation is a journey to future inventions which would be a breakthrough for humanity. It’s a initial step , I may be allowed as international visiting fellow

Fundamental issues and challenges

Difficulty To seek a PI for post doctoral training as a beginner as international visiting fellow non resident us citizen , there is no proper way to access this. Difficult to reach out . Please make the process simpler.

Existing NIH policies, programs, or resources

Still waiting to be initiated for the training program

Proven or promising external resources or approaches

There us need to look into the process of selecting PI and application submission process. .

Response 1828

Perspectives on the postdoc roles and responsibilities

It is a continuation of development to build the skill set/specific interest to move to the full professional stage in ones career. Expanding career network and exploring career next steps and opportunities.

Fundamental issues and challenges

The salary entering an academic position. Lack of available positions.

Low salary for postdoc positions especially when cost of living increases rapidly and the salary does not quite correlate to cost of living (especially in the DC region).

Industry post docs have more competitive wages and benefits.

Existing NIH policies, programs, or resources

[redacted for anonymity] post doc perspective--offer the following

Full benefits (retirement, 401k while training)

Increased wages

if required to be in the DC area-affordable housing options or flexible with commute if having to live in a long-distance location to afford to be in the area

Assistance with taxes (big issue)

Being able to apply for student loan repayment during [redacted for anonymity] postdoc experience or offering ways to repay loans through research or service.

Proven or promising external resources or approaches

No response

Response 1829

Perspectives on the postdoc roles and responsibilities

I started a postdoctoral position thinking it would be fundamental for developing my scientific independence and research ideas. After several years in this position, I realized that, basically a postdoc position is more about doing your PIs ideas and following their line of research. I think that the requirement of doing postdoctoral training to become a independent researcher is totally unnecessary.

Fundamental issues and challenges

Postdoc salaries are absurdly low, with minimal benefits. Postdoc salaries should start close to $100,000. Less than that is just cheap labor and undermines postdocs’ expertise.

Existing NIH policies, programs, or resources

Set an unprecedented national and universal example by increasing salaries substantially.

Stop saying that doing so is impossible. People are tired of such excuses. The money is there, and if it is not, find it.

Proven or promising external resources or approaches

Increase substantially postdoc salary scale range and do not fund research institutions that do not comply with NIH guidelines in salary range.

Response 1830

Perspectives on the postdoc roles and responsibilities

The postdoc should be viewed as a transition position from dependence as a graduate student on mentor guidance, to scaffolding of the independence gained in a faculty position. An opportunity to gain new skills and test the waters of academia while still supported (financially and intellectually) by a more established researcher.

Fundamental issues and challenges

The challenges with recruiting and keeping postdoctoral trainees has a lot to do with a lack of faculty positions available for them to transition to—and a significant underfunding for their skill and education level. PhDs are incredibly well-trained and valuable but they are underpaid and overworked with little hopes of transitioning to a full time position. That lifestyle is not desirable to many new PhDs who have been paid minimally for 4-8 years or who have already held a post-doctoral position for several years with little success on the academic job market.

Existing NIH policies, programs, or resources

Salary caps for both graduate students and post-doctoral researchers should be raised—I understand the need for maximums but requiring that trainees who are highly skilled and would be desirable in the private sector make so little is a disservice to the scientific community and diminishes the number of individuals from disadvantaged backgrounds who may be able to survive on those wages. Faculty over a certain age or career duration should also be prioritized for funding—those individuals often simply employ a small army of trainees and coast on their reputations rather than contribute meaningfully themselves.

Proven or promising external resources or approaches

I am not familiar with any proven or promising external resources or approaches that could help with these problems at this time.

Response 1831

Perspectives on the postdoc roles and responsibilities

The academic postdoc position presents an opportunity for the trainee to expand and present ideas in a situation where they can direct research ideas in to potential future opportunities beyond what their lab may focus uniquely on. I view it as a stepping stone to the next position whether that is academic, government, or industry. As much as the position presents for growth and advancement of skills I would not say that it is currently viewed as a lucrative or important position unless you wish to go into academia. The low comparative pay versus what your skill level would entice makes the position one in which you are sacrificing known value versus future value.

Fundamental issues and challenges

The postdoctoral position is currently viewed as a step back in research. The ability to advance in academia to a Professorship position is not straightforward and many graduate student trainees see the postdoc step as wasted time. If the end goal is to move to industry or government and you already have the skills necessary, you are potentially taking a $40k+ pay cut for postdoctoral training. With the current base pay of postdocs in the ~$50k range and no employee matching for retirement it’s a giant struggle for research interest versus well being and financial stability. With the current pay rates a graduate student that chooses to go and do a postdoc is sacrificing up to 12 years of their life for a wage far below their

expertise. Paying graduate students and postdocs a liveable wage that can keep pace with inflation should be addressed. As it stands, there isn't an incentive to stay in academia and we stand at the edge of "brain drain" for individuals that are interested in academic pursuits.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

Payscale. You're asking grad students to go from a woefully underpaid wage to a postdoc where we get slightly more money but are still severely underpaid. It's not a mystery why someone would choose a ~$100K+ job for their skills versus a ~$50K job. Until salary reflects the time investment that we put in, grad students will continually choose more lucrative options. Academic research and the freedom is enticing, but we need a salary to justifying the cost/benefit equation.

Response 1832

Perspectives on the postdoc roles and responsibilities

When I entered my postdoc, I viewed it as an opportunity to

1. gain new and additional expertise that will contribute to my ability to conduct the independent research I wish to do, and
2. publish more manuscripts and attain k-level grant funding, both for the purpose of making me a more competitive applicant to extremely limited and competitive faculty positions.

This is still how I view what it should be, but it has not been my experience.

Fundamental issues and challenges

1. Salary and benefits. Pay needs to be commensurate with education, experience and cost of living. It also needs to include guaranteed maternity/paternity leave, good healthcare, and retirement fund options. I've heard the argument that one's willingness to endure the postdoc salary is a "weeding out"process, suggesting that one is not dedicated to research if they aren't willing to be paid inadequately to pursue that research. This is not so different from telling a woman who is being paid less than man that she's clearly not as dedicated as him if she's complaining about her salary. Moreover, the truth of the situation is actually the opposite. The current system is exploitative and explicitly relies on the passion and self-sacrifice of people who are deeply dedicated to solving this country's problems (for me, chronic pain and opioid addiction) and to promoting a more just and well society.
2. Time and labor. There need to be pre-defined limits to the extent to which postdocs can be used as laborers to complete things like running participant assessments for a PI's study. While this is, in part, a negotiation between a postdoc and a PI, the power hierarchy in that situation prevents a postdoc from successfully advocating for themselves and NIH has the ability to protect the postdoctoral experience from morphing into labor for a PI.
3. Grant cycle timelines. If I submit a Cycle 2 K-award application, I'm locked into another year as a postdoc just waiting to hear if it gets funded. If it doesn't get funded, the next feasible cycle to submit my revised application is cycle 1—but I again won't know if it's funded until 1-4 months into the next academic year. So, I'm once again locked into another year of postdoc, waiting to hear if my grant got funded.

Existing NIH policies, programs, or resources

1. R01 funding needs to be high enough to support the entire team needed to conduct the study. This is relevant to issues of both salary and labor for postdocs. Without question, the R01 needs to be large enough to support a higher postdoc salary. It also needs to be large enough to support adequate salaries for CRCs, research assistants and associates, etc. alongside higher postdoc salaries, so that postdocs don't get saddled with the responsibilities that theoretically belong to those other roles. The roles **and responsibilities** of a postdoc also need to be clearly defined by NIH for PIs. Postdoc time should be protected for learning new skills, analyzing data, writing manuscripts, and taking the steps necessary to advance to the desired next stage of one's career.

2. Postdocs should get immediate acceptance into the student loan forgiveness program. And if this doesn't happen, postdocs should at least not be penalized for their mentor's funding status. The salary sacrifice of a postdoc—even if the salary is raised in the future—should be curtailed by guaranteed support for repaying student loans from our many years of education.
3. Several changes need to be made in the context of postdocs agreeing to work with early-stage investigators. It is not possible for a postdoc to get the same mentoring from an ESI as they would from a more senior PI, which disincentivizes postdocs from joining new labs run by ESIs. But ESIs need postdocs to join their labs so that they can establish a track record of training postdocs to go on to establish independent careers. This catch-22 is made worse by the fact that postdocs who do join new labs really don't get the best mentoring, thereby making it harder to go on to establish an independent career. Solutions for this are in the next section.

Proven or promising external resources or approaches

Continuing from last section:

1. Every ESI should be paired with a senior faculty member who is immediately assigned as a co-mentor to incoming postdocs. Any postdoc joining a new lab should expect to be co-mentored from the start, without having to
    a) seek out their own additional mentoring for adequate expertise and
    b) navigate asking a new, personally identified co-mentor for things (grant feedback, career advice, etc) the ESI primary mentor should theoretically be providing.
2. Postdocs should receive some sort of incentive to join newly established labs with ESIs as primary mentors. Some ideas could be extra salary support (for both the postdoc and ESI), protected funding for travel to conferences and meetings that doesn't depend on the PI, directed funding for open access publications that doesn't depend on the PI, and variable grant reviewer expectations for applicants in new vs. established labs. A postdoc coming from a lab whose PI just finished an R00 and is trying to get an R01 has access to substantially less data and fewer resources (and thus also opportunities for manuscripts) than a postdoc coming from a lab whose PI is about to retire.

There should also be some sort of protective system for postdocs competing for career development awards that faculty are also applying for (eg, k01, k23), similar to the protections for ESIs competing with more established faculty for R01 funding.

Response 1833

Perspectives on the postdoc roles and responsibilities

It feels like a glorified graduate student.

Fundamental issues and challenges

The salary is way to low.

Existing NIH policies, programs, or resources

Increase the salary and provide unionization.

Proven or promising external resources or approaches

Working environment

Mentoring

Response 1834

Perspectives on the postdoc roles and responsibilities

What I would like it to be: training to become an independent researcher. What it actually is: a cheap way to produce data from someone else. Often very low autonomy, little skills development—eg not learning to write your own grants, manage your own budgets etc, but instead being a glorified experiment robot for an established PI.

Fundamental issues and challenges

Not being able to start your life until after potentially 10+ years. Low job security, moving location = not being able to settle with a partner / have stable friends / start a family. Long hours, lack of clear career progression.

Existing NIH policies, programs, or resources

I am not familiar enough with these to answer this question. I am currently a graduate student in the UK and although I would love to do postdoctoral research with the fantastic institutions in the US, this is unlikely for me given the lack of pay, job security, work culture, etc etc, that are particularly problematic in the US.

Proven or promising external resources or approaches

Shorter postdoc periods. Eg awarding less PhDs, or more faculty jobs, or setting a low max duration for becoming faculty (making allowances for starting a family, illness, etc)—so that this period is only say 5 years instead of indefinite. Better support and structuring into alternate careers.

Response 1835

Perspectives on the postdoc roles and responsibilities

As a scientist we lay down building blocks of scientific research. We work hard to make new discoveries for the development of nation and mankind as well.

Fundamental issues and challenges

The postdoctoral scientist are treated as skilled labours with the minimum salary. The salary barely meets the basic requirements rather than to meet certain lifestyle. The struggle to balance emotional and financial wellbeing has become an integral part of a postdoc. Hence industries pharma and other options seems more attractive than acadmia.

Existing NIH policies, programs, or resources

A huge upgrade of salary is the dire need of the postdocs to carry a successful research career. Relaxation in the immigration rules could also play a significant role in shaping the mindsets of researchers. The salary must be upgraded to at least 80K to begin with. This will ensure a comfortable career option for an individual to pursue a career in science.

Proven or promising external resources or approaches

One of the most difficult thing is to maintain work and personal wellbeing as a postdoc researcher. The postdocs work hard upto 12-14 hrs including weekends without any extra benefits makes their personal life down to nothing. Financial stability is the foremost requirement of a postdoc in current situations. Handsome salaries are being payed by industry and other jobs with several perks for doing extra or overtime works. Thus it become worth putting extra effort if one is getting payed for it. But this aspect us missing in a postdoc job. There in no comparison for the amount of effort put by a postdoc fellow as compared to a 9-5 job. But there is a huge difference in the payroll. To sum up now it is a high time to consider a huge upgrade in the postdoctoral salary and other benifits.

Response 1836

Perspectives on the postdoc roles and responsibilities

Performing significant contribution to the lab’s output, trouble shooting, producing new research ideas and projects, mentoring graduate and undergraduate students, supporting the PI in grant applications and administrative duties

Fundamental issues and challenges

Currently the biggest issue for postdocs is salary. Living expenses have been increased a lot lately while salaries are not. And despite the NIH guidelines for stipends, universities don’t stick to them. The general feeling among postdocs that I observe in social media is anger and frustration. Having a family, which one usually wants to start at that age and paying for daycare is just not possible when both parents are postdocs.

Existing NIH policies, programs, or resources

Child care vouchers, fully paid maternity leave, funds to sustain a family

Proven or promising external resources or approaches

No response

Response 1837

Perspectives on the postdoc roles and responsibilities

I would say that the academic postdoc is a transitional position between learning how to be an independent scientist as a PhD student and learning to run a research program or group as a PI or group leader in industry. Postdocs are key people in the running of successful labs, bringing experience and helping develop more junior trainees while being very productive themselves. Over time, senior postdocs should have the skills, experience, and publications to move on to higher positions in academia/industry.

Fundamental issues and challenges

There are so many. First, the poor stipend/salary is extremely difficult to swallow for highly educated scientists who have succeeded throughout their lives and are often at or near their thirties and interested in buying house, starting families etc. It is really difficult to argue they should stay in academia when

1. industry often pays twice as much or more,
2. there is no guarantee or even good chance of become a PI following a postdoc,
3. the senior scientist academic position for those who do not get a PI position have generally poor job security and poor pay, and
4. the time as a postdoc is often at least 5 years. it is very challenging to recruit postdocs with these challenges, and when you combine that with the increasingly overwhelming expectations of many journals and PIs, it is often looked upon like you get a PhD only to spend another PhD's worth of time killing yourself for a low percentage chance of another relatively low paying job.

It is very discouraging, especially for the US citizen or permanent resident PhDs who often have lots of other options.

Existing NIH policies, programs, or resources

Obviously increasing the pay is a start, but causes secondary problems related to not enough money to go around. I think that on the other end the NIH ought to cap Investigator direct costs at something reasonable (maybe $1M) to open up part of the pie for paying postdocs more. Separately, if the NIH was able to take a more active role in publishing, focusing on getting all of the data produced by taxpayer dollars published, and secondarily, not wasting billions of taxpayer dollars paying publishing companies that make massive profits off of our work and taxpayer dollars, this could save a ton of money that could be reinvested in paying postdocs better. A second area that could easily be changed is to really push that postdoctoral fellowships are public service. In truth, they are, but rarely do you hear anyone say this, and it should be a more prominent focus to make sure that postdocs feel like they are providing a service to the country/world by making scientific discoveries and sharing them with all. Finally, finding ways for senior scientists (e.g., postdocs who do not become PIs) to better earn their own funding would be very helpful, as there are plenty of wonderful scientists who do not want to lead a lab. Having a clear career path for these scientists would make the prospect of a postdoc less bleak.

Proven or promising external resources or approaches

No response

Response 1838

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

The salaries are way too low!

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1839

Perspectives on the postdoc roles and responsibilities

Performing quality research and gaining knowledge about unexplored areas in the field of interest.

Fundamental issues and challenges

Most fundamental issue:

1. The salary of a postdoc is very low, its hard to maintain a family and do any kind of saving. Since we are in a phase of life where we want some kind of stability, we must be secure on the financial aspect of our lives.
2. It's hard to sustain in academia because of the limited number of faculty positions. Specially if you are not a US citizens or a green card holder.
3. Quality of life is represented by the pay scales as well. We request to increase the salary of a postdoc fellow since the industries are paying decent amount of money for the same qualifications.

Existing NIH policies, programs, or resources

Please introduce more grants and funding opportunities for non US citizen or permanent residents.

Proven or promising external resources or approaches

1. Hike in the salary.
2. International work environment.
3. Freedom to work.

Response 1840

Perspectives on the postdoc roles and responsibilities

Roles and responsibilities as an academic postdoc involve starting a risk system and publish a paper.

Fundamental issues and challenges

Postdoctoral trainees feel abused. Postdoctoral training is not structured and supported as the graduate studies. Academic toxicity, discrimination, the importance of being the best in the lab, no job security. Postdocs start the project from scratch and are being given to help the career of other folks, letter of recommendation, evaluation system (papers and grants) to get the job. Risk projects can take longer than 4 year deadline of K99.

Existing NIH policies, programs, or resources

Remove K99 restrictions, Bring more fellowships for internationals

Proven or promising external resources or approaches

Restructure postdoctoral training with checkpoints, Bring more funding for international postdocs

Response 1841

Perspectives on the postdoc roles and responsibilities

I think that it is a poor return on investment.

Fundamental issues and challenges

Low pay, poor benefits, poor work conditions, low job security, position dependent on grant funds

Existing NIH policies, programs, or resources

Higher pay with better benefits and job security. Better training for jobs outside basic science research

Proven or promising external resources or approaches

Complete restructuring of what a post doc is

Response 1842

Perspectives on the postdoc roles and responsibilities

It means a chance to take charge of the type of experiments to be done and design an optimal workflow

Fundamental issues and challenges

Salary does not invest in our future (retirement) or peur present (too little to sustain a family). Current salary only allows people who have working partners to continue a postdoc and often there is no salary growth

Existing NIH policies, programs, or resources

Improve pay band. Allow for retirement package contributions and require salaries increase to allow a decent life

Proven or promising external resources or approaches

Improve work environment and work incentives. Other jobs get bonuses, pay raises, paid holidays, childcare etc. Do better! Post docs are humans who also want to build families and a worthy life

Response 1843

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

The fundamental issues challenging recruitment and retention of postdoctoral trainees into academia include, primarily, financial incentive and job prospects. Many individuals coming out of graduate school don’t want to submit to 2-7 years of making $50,000/year, especially as most of us are at an age at which we have families to support. Furthermore, after we finish our fellowships, there is no guarantee that we will get a job in an academic setting or that our jobs will be secure (i.e., not adjunct or teaching positions only). Industry positions that do not require a postdoctoral fellowship are available, all but guaranteeing long-term job security, and offer more money than most early career faculty make. Unless you are someone whose research area of interest is highly specialized/niche and therefore not of interest to pharma/biotech companies, industry jobs are better paying and more secure, and there are more of them than there are available academic positions.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

Remove salary caps on NIH-sponsored F32 and T32 fellowships (make them salary minimums) so salary depends on the funding of the institution/researcher and is dependent on cost of living (e.g., $50k in Iowa is different than $50k in NYC). Introduce fellow-to-faculty pipelines as part of the receipt of F/T awards,

wherein the host institution agrees to hire fellows in good standing who receive independent funding (i.e., K award or other) in early career, tenure-track positions. Provide incentive (e.g., subsidies/tax credits?) for academic institutions to increase the number of early career, tenure-track positions to keep researchers in academia.

Response 1844

Perspectives on the postdoc roles and responsibilities

The post-doc training should include several components including research, independence, and professionalization. (RESEARCH: This should be an opportunity for just phds to attain additional skills, which will synergize with the ones developed during the phd that will allow them to build a niche they can bring to their careers) (INDEPENDENCE: phds should attain grant writing, paper writing, and leadership skills, which they will need when starting a lab) (PROFESSIONALIZATION: This training is on how to prepare persuasive talks, improve writing quality, behave in academic contexts as a faculty.)

Fundamental issues and challenges

All of the problems in postdoc recruitment, retention, and quality of life revolve around a dearth of mentorship by investigators that at every opportunity extract from trainees without fulfilling their obligations as mentors.

Lack of mentorship in RESEARCH:

1. Labs often over rely on post-docs for research, and hire them for what they know already because they do not require training furthermore, there is little thought into what is next for their trainee.

INDEPENDENCE:

1. Labs increasingly just rely on postdocs, as such, there are no students for the postdocs can help mentor and this means that they do not attain mentorship skills
2. Grant writing involvement is kept at a paragraph level, figure and doing menial tasks that do not enrich the postdoc. Additionally, post-docs are typically not included as key personnel, which would help their ability to attain an independent position.
3. Post-docs (and grad students) rarely give talks at conferences. Instead, they give poster presentations. While this approach leads to better conference programming; it also implies that trainees enter the job market with little experience and presentation skills.

PROFESSIONALIZATON: oftentimes trainees are hidden when guests come to labs, and they are just there to be subservient to the PI. The goal should be to make independent investigators, as such, they should be given a seat at the table, included in professional dinners, and PIs should work to help them develop the networking/introduce them to a network.

The above sounds like a lot for a postdoc. However, many (including me) are turning down 6 figure jobs to take a 50k dollar job for the promise of an academic career. The pay cut should imply mentorship and a path towards this is part of the deal. Finally, we need to make more academic jobs available.

Existing NIH policies, programs, or resources

1. Stop calling employees ‘trainees’ to pay them less. We should rely on research from institutions and not academic ones. These would ideally hire FULLTIME researchers with fair pay.
2. Help academic institutions train:Provide more training grants whose sole purpose is to create an educated workforce. Include funding opportunities where half is research approach the other half explaining how this research will train students to be the best. These trainees can then be employed by the research institutes.
3. Tie funding to pell-grant recipients:The overfunded institutions have less than 10% pell grant recipients and about 30-40% of students receive pell grants. This means that public funds serve a small number of already over-resourced individuals. Since we are using public funds, we should refuse to fund them unless they train a proportion of pell-grant recipients that is commensurate with our population. In other words, if a faculty wants public funding, they should serve the public. If the PI’s institution does not serve the public, then, we should encourage them to move to one that does.

4. As a POC and URM.PLEASE STOP these merely symbolic DEI efforts. The symbolic DEI efforts are generating a culture of resentment, and at the same time are not changing anything. I just came back from a conference, where I was the only POC who is also a URM faculty. People are not inviting me to give talks or collaborate because they want a more diverse pool of participants. Instead, the number of microagressions have increased where people complain about DEI. However, there are no actual material DEI efforts, just symbolic overtures to 'diversity.' The costs of symbolic DEI is material though, since those who are in power and complaining about DEI are the ones who will be voting on my tenure case in a few years.

Proven or promising external resources or approaches

Mentoring: Tie supplemental funds to mentoring opportunities. Some institutes force supplement awardees to apply for fellowship funding as part of their contract. To be frank, a requirement like this one is the reason I have a faculty job. My 'mentor' was forced to help me apply for funding, and I received what I needed to succeed.

Job satisfaction: Post-docs (and trainees in general) need more job opportunities. We need to make sure our undergraduates are not just labeling data, graduate students conducting experiments, and postdocs brining expertise to labs. Grant mechanisms should have an approach like section that involves describing how each activity will enrich the trainees that they put in their budgets. Furthermore, an environment metric should include quotas at academic levels of trainees that make sense. In other words, a lab with 4 postdocs and a grad student means that the faculty is helping 4 trainees get faculty jobs. However, there is only one student to be mentored. Also, realistically are there 4 faculty jobs out there going to one faculty group? Note: The post-doc is a position where people expect to get a faculty job afterwards).

Response 1845

Perspectives on the postdoc roles and responsibilities

The postdoc seems unnecessary for the vast majority of people. Really, only useful for people who want to gain new expertise, who really care about changing fields, or people who want to pursue academic aspirations. It seems though like academia relies on postdocs too heavily and thus isn't fully honest about this, and lead people to do postdocs unnecessarily. Now more people seem to be realizing this and are opting to not to do a postdoc because it is not necessary and under the current system heavily exploits you.

Fundamental issues and challenges

Pay is poor relative to other Job prospects. Job prospects that justify a postdoc training experience are not plentiful and/or desirable. Further academic jobs that do exist are in a system that is not keeping up with the times. For example, ro1 funding rate decline, ro1 grant size not changing in 20 years despite the cost of almost everything increasing.

Existing NIH policies, programs, or resources

Make academic career tracks more desirable. Increase grant sizes, increase funding lines. Increase postdoc pay. Provide more PhD to postdoc transition awards.

Proven or promising external resources or approaches

No response

Response 1846

Perspectives on the postdoc roles and responsibilities

Professional development needed to achieve independence. A PhD provides in depth training in a specific topic, postdoctoral training provides broader training to equip you for independence.

Fundamental issues and challenges

The pay and location constraints are the biggest issues. $50k starting salary as an NIH postdoc vs a 6 figure industry position is becoming more and more disparate. Plus, moving to a new city, commonly with

no support, during child bearing ages should not be the normal expectation. That is not common in any other field.

Existing NIH policies, programs, or resources

Increase pay, better child care/family leave support, provide remote training when appropriate (not always feasible).

Proven or promising external resources or approaches

No response

Response 1847

Perspectives on the postdoc roles and responsibilities

The postdoctoral position is a time for young scientists to apply their research skills to work independently, in preparation for their career either as an academic scientist, in industry, or serving other sectors such as government. I view the postdoctoral role as one in which the postdoc already has the scientific skills needed for a science career at a very high level, but could use some additional training in soft skills that they may not have gained in their graduate or undergraduate study. Science communication or SciComm should ideally be part of scientists' coursework before the postdoc, but since it is not, I am writing to suggest that it be included in the postdoctoral training. Explaining science is part of a scientist's job, whether it's to fellow scientists, scientists outside of the field, important stakeholders in industry and government, and/or the general public—even just talking to friends and family at Christmas dinner.

I believe formal science communication coursework should be an integral part of any training grants for junior scientists [whether for training (T), fellowship (F), or the career development awards (K)]. Training grant funds could be used, for example, to expand existing Science Communication courses or setting up new programs to help improve junior scientist communication skills.

These recommendations are supported by the just-released 2023 Research!America poll that found: "There is robust bipartisan agreement that scientists' job should include communicating their research to the public (86% of Democrats, 77% of Republicans, and 77% of independents say "yes")." Trust, credibility, and funding for scientists all depend on good SciComm skills—and it is critical that junior scientists become very good at talking to the diverse public(s) who need to hear their messages.

Fundamental issues and challenges

Improving science communication curriculum as a postdoctoral trainee can create new opportunities, breaking research silos and helping postdocs interface more productively with various stakeholders, including but not limited to: their supervisors, potential employers, members of the general public, and so on.

Existing NIH policies, programs, or resources

NIH could create a science communications requirement for the postdoc which could be completed via various means, such as blogging about science, taking a seminar, or via attending various lectures. It doesn't have to be complicated. I recognize that postdocs already work a lot and have a lot on their plate; however, a small amount of communications training will go a long way and is worth the effort invested

Proven or promising external resources or approaches

Fancy Comma, LLC, is my science communications company. We are part of a much larger ecosystem of scientists, science communicators, communications professionals outside of science, science journalists, and more, who are dedicated to developing a science communication training program for junior scientists (and people studying science at any level in higher education). We would love to be a partner and work with NIH to help build a SciComm ecosystem in science to improve the conversation between science and society, help make science more inclusive, and for many other reasons. You can learn more about us at www.fancycomma.com.

Response 1848

Perspectives on the postdoc roles and responsibilities

As a former NIH intramural postdoc, faculty member, and Principal Investigator of an NLM T15 training program, I have seen both the promise and the peril of the academic postdoc model. Much of the difficulty with academic postodcs stems from differing perspectives on the definition of the roles and responsibilities of the position. To some, the role of the postdoc is to be a productive researcher—the engine of a lab's research. I believe this role is unsustainable and inappropriate.

The primary role and responsibility of a postdoc should be to grow their own career. In most cases, this will be consistent with the goal of the mentor and the lab to conduct productive research and to publish papers. However, the timeline is critical: the postdoc should be starting their position with the goal of finishing, charting a path that will lead not only to published papers but independent grant submissions—ideally for K-flavored grants, within a period of no more than 5 years.

Fundamental issues and challenges

It is abundantly clear that the most fundamental challenge facing postdocs is compensation. Recent research has clearly shown that stipends are not sufficient for postdocs to make ends meet, particularly at a time of life when many are having children and facing significant family-related expenses. Although compensation is a national issue, it is likely a particularly difficult problem in more expensive cities where major biomedical research institutions tend to cluster.

The impact of low stipend-levels is a problem that may be felt differently across fields. In my field—biomedical informatics—we routinely recruit undergraduates with degrees in computer science and related fields. These students bring expertise that has often been in high-demand. Asking them to spend 5 years of graduate training and 3 years of postdoctoral training at stipends that are 1/3 or less than those that they might make in industry is not particularly sustainable. Perceptions of poor career prospects present related challenges. Graduate students and postdocs are well-aware of both the limited prospects for being hired in faculty positions and in the significant demands of working in these roles. To attract more qualified postdocs and to improve their quality of life, we must show that there are real prospects for satisfying careers ahead.

Existing NIH policies, programs, or resources

There are several changes that NIH might make:

1. Postdoc stipends should be raised to levels appropriate for raising families in locations where biomedical research labs are found. These changes should be made without jeopardizing the spending power of current or future grants. Specifically, any dollars that are added to stipends for current or future grants should be provided through overall increases to existing (or future) budgets, not be shrinking the dollars available for the rest of the grant.
2. Postdoctoral training programs should be structured to emphasize the importance of appropriate career development, with a range of rewarded outcomes that are aligned to the realities of employment prospects. Specifically, NIH must recognize that many postdocs will not go on to be research faculty: "alternative" options such as faculty roles at teaching institutions, senior research scientist positions, or industry positions should be considered "first-class" outcomes and successes of post-doctoral training. Incentivizing training program directors to encourage postdocs to explore a broad spectrum of possible careers will help these programs more honestly attract postdocs and more realistically prepare them for likely career outcomes.
3. NIH should work to establish accountability from faculty and to ensure that postdocs are treated well. Tales of postdocs who are abused by PIs who don't wish to lose valuable personnel or ideas are rampant. To protect postdocs, and therefore to make positions more desirable, NIH should explore ways of tracking postdoc careers, measuring lengths of time as postdocs, and even tracking the performance of individual faculty members in mentoring postdocs. This may be very difficult to do without creating a paperwork nightmare: NIH should work to develop methods that track these key details without creating burdensome paperwork requirements. However, good data on who succeeds, how, and why would be very helpful.

Proven or promising external resources or approaches

Listen to the postdocs. NIH must systematically engage current and recent postdocs—including those who have left academia—to understand their concerns and needs.

Response 1849

Perspectives on the postdoc roles and responsibilities

I view it as a time to further my training with more autonomy than in graduate school and with the ability to learn new skills/techniques

Fundamental issues and challenges

Not paid enough to live in the cities where the best research is happening. I have been a postdoc now for over 7 years and my salary hasn't changed substantially. But this is also happening during a time when I've had 2 kids, so now my costs have gone up.

Existing NIH policies, programs, or resources

I think increasing the time for ESI status is imperative. Things just take longer to get published, which is the currency for our work. And higher pay would be amazing.

Proven or promising external resources or approaches

No response

Response 1850

Perspectives on the postdoc roles and responsibilities

I feel that without long term prospects and some benefits, postdocs are a waste of time after finishing the PhD. Within a month of starting mine, I regretted it. I took a job in industry and never looked back.

Fundamental issues and challenges

Post docs produce incredibly high level work for insulting pay and job security, as well as long term career prospects. If there is a shortage, maybe learn from this.

Existing NIH policies, programs, or resources

Make the position a full time position with benefits and long term career prospects.

Proven or promising external resources or approaches

Make it like any other job. I really do not think this is a complicated or difficult issue to understand. Unless one is independently wealthy, there are very few benefits for any person wanting to build a life. No benefits, can't buy a house, it's shameful.

Response 1851

Perspectives on the postdoc roles and responsibilities

My perspective on the academic postdoc was that my responsibilities were to

1. Expand my technical skillset to improve my capability to approach scientific questions in diverse ways;
2. Assume more responsibilities so to be viewed as an independent scientist that can succeed outside of your PhD institution and without your PhD advisor's guidance; and
3. Gain mentorship and networking opportunities to transition to an academic position, or if desired, a non-academic position The academic postdoc is meant to be a time to discover and test your ability to act and think independently of the confines of your dissertation work, but with sufficient guidance and support from your postdoc advisor and institution to ease the transition into an investigator or industry scientist role where you will be operating with increased ownership and responsibility of your work.

Fundamental issues and challenges

1. The flat payscale for postdoctoral fellowships needs some tinkering—as someone that postdoc'ed in a high cost of living area, my colleagues postdoc'ing in lower cost of living areas faced significantly less burdens than I did, which I hardly find equitable. This will doubtlessly aid in recruitment, as my postdoctoral mentor has have had difficulty convincing prospects to join despite the institution's reputation due to high cost of living. Thus a cost adjusted scale may be helpful.
2. Regarding retention, without academic positions at the investigator level available, there may be less motivation for any trainee to enter postdoctoral training at an academic institution as industry can offer more competitive pay and more assurance that the training experience can be utilized to transition into a role at a company, at the site of training or elsewhere.
3. I think it's fantastic to have exposure to various levels of grant security/insecurity during training to see the reality of academic life, but I think federal postdoctoral funding likely needs to increase somewhat outside of stipend and institution support, and into the ability to purchase limited scientific equipment/reagents so a postdoctoral fellow can gain independence and test their scientific abilities earlier. As a previous K99/R00 recipient, I thought even the limited amount of spending money for research supplies made me feel far more independent than when I was on my postdoctoral T32.
4. I think if postdoctoral trainees are not seeking a professorship and wants to be an academic project scientist or similar, a defined pathway should be clearer so the individual can exit their training period and gain more financial stability and compensation earlier.

Existing NIH policies, programs, or resources

I think the existing policies and programs offered by NIH are (broadly) sufficient, and the postdoctoral training ecosystem is often significantly shaped by the postdoctoral mentor and home institution, and thus is unique and difficult to apply broadly.

Proven or promising external resources or approaches

I believe NPA's 2023 survey regarding postdoctoral barriers is sufficient for informing the obvious issues that need to be addressed.

As an aside, if there is anything that could enhance the academic postdoctoral training ecosystem, it is not necessarily a guarantee of an academic job at the end of the training, but to encourage and retain the romanticism, inventiveness, and idealism of scientific inquiry. I don't believe it's appropriate to compare all metrics of the academic postdoc to industry or government postdocs, as what is offered by the experience of the academic postdoc are wholly different. It is also not to say that all three sectors cannot have some opportunities for cross-disciplinary collaboration (as appropriate) so there's flexibility that the postdoctoral training experience in one sector does not preclude the ability to succeed in the other.

I think it would be preferable if another RFI is offered regarding the academic system as a whole, as I believe difficulties in postdoctoral recruitment and tenure-level academics leaving are part and parcel and there's far greater issues that need to be addressed for the sustainability of the academic ecosystem.

Response 1852

Perspectives on the postdoc roles and responsibilities

For me, a postdoctoral position is an important position to enhance my knowledge and understanding of research. It helps me improve myself as a scientist.

Fundamental issues and challenges

The main challenge postdoctoral trainees face is economic, especially when they have to support their families.

Existing NIH policies, programs, or resources

The salary hike would be great to help them focus on their work.

Proven or promising external resources or approaches

No response

Response 1853

Perspectives on the postdoc roles and responsibilities

I consider it like a medical residency equivalent. You're independent and fully trained, are able to produce efficiently, bud also are still learning some about how to get grants or run a lab.

Fundamental issues and challenges

The pay!!! I'm telling you, if academic post docs got paid more many would stay. Industry jobs pay two times as much, and even if someone loves working in academia they have to leave for that difference in pay.

Existing NIH policies, programs, or resources

Increased pay scales or allowing PIs to pay whatever they want with NIH funds

Proven or promising external resources or approaches

Job satisfaction and sustainability with increased pay

Response 1854

Perspectives on the postdoc roles and responsibilities

The Postdoctoral position gives a researcher the time to

a) Assess if academia or industry suits them better
b) Wrap up PhD publications
c) Lean how to mentor students
d) Learn how to write applications for funding and generate narratives around novel ideas
e) Learn how to teach
f) Learn how to run a research group.
g) Extend a professional network
h) Become independent

This all depends on the mentor and length of funding.

Fundamental issues and challenges

The NIH salary minimums are so low, I have recent graduates (no graduate degree) earning more for similar, but much junior positions.

I work in AI in medicine and industry offers 3-4 times as much. It's impossible to retain postdocs under those conditions.

At the same time, postdocs want to move on to industry or academia asap, and I'm seeing too many getting positions when they aren't ready. The training is important but junior researchers are desperate to skip the postdoc years. I'm not seeing strong applicants for faculty positions, even at the most prestigious universities. This leads to superficial research. It seems the training element of a postdoc is missing.

Existing NIH policies, programs, or resources

The minimum salary should be field specific and raised. (I know it's a minimum, but many universities take it as a maximum in the interests of 'equity'. While this is noble, and ib would love to see us all paid the same for the same work, it ignores the realities and means certain fields cannot hire good talent. It's a free market and we have to respond to those pressures.

Proven or promising external resources or approaches

Coupling doctoral positions as a ramp to faculty positions at year 3-5 depending on progress, with a joint mentorship team between the host institution, one external institution, and a program officer.

Response 1855

Perspectives on the postdoc roles and responsibilities

My own postdoctoral experience was completely worthless, provided me with plenty of opportunities for developing severe mental illness and hones my skills as an extreme individualist, none of which helped me in my (successful) career in industry. It was a requisite for a higher title than associate.

Fundamental issues and challenges

Pay, rampant mental abuse by PIs and other faculty, survival of which is considered a badge of honor. Worthless skill sets are emphasized, lack of funding in labs mean sharing out of date equipment, data forgery and manipulation is rewarded with higher positions in academia.

Existing NIH policies, programs, or resources

Industry should be carrying post doctoral research for the foreseeable future, while the absolutely foul and unaccountable university-led system in the US is canceled completely. Paying highly qualified people $40,000 whilst working them to near suicide is shameful.

Proven or promising external resources or approaches

The Genentech postdoctoral program is outstanding as I have witnessed first hand. There is camaraderie and at least avenues for young trainees to support each other, should their (still unfortunately not-wholly accountable) mentorship go awry.

Response 1856

Perspectives on the postdoc roles and responsibilities

I view my role as a postdoc as both an independent scientist and a trainee. I am still in training to become a PI by learning more about how to conduct research, run a lab, mentor other trainees, and apply for funding. However, postdocs also have Ph.D.'s and are experts in our fields, and should be given freedom to pursue independent research projects. I also see my role as a mentor to graduate students and other trainees in my lab. I also see my position as an opportunity to build a research program, since I am working on something related to but independent from my PI's main work, and would like to continue this line of research as an independent PI someday. Lastly, I see it as an opportunity to become more competitive for a faculty position by publishing more papers and acquiring funding.

Fundamental issues and challenges

My postdoc pay is livable, but not competitive with alternative career options such as a career in industry. I did not look into industry careers myself, but anecdotally I hear a lot of postdocs leaving academia because they can get a job in biotech or a related field and get paid much more. I also think there tend to be fewer benefits for postdocs compared to other jobs that scientists with Ph.D.s are qualified for (e.g., parental leave, retirement matching). There is also less job stability as a postdoc, since contracts are often year-to-year and depend on PI funding. Many postdocs are in our late twenties or early thirties, or older, and are therefore at a life stage where we are thinking about starting families, saving for retirement, etc. However, it is difficult to do this at the postdoc stage since you know you will likely move again at least one more time in the near future, but you don't know when. Also, depending on where you live, the postdoc salary may not be enough to support the cost of living and raising a family. I also think seeing other postdocs struggling on the job market is discouraging and makes it stressful to be a postdoc. While I am enjoying being a postdoc for now, I know it is a temporary position and I would like to get a faculty job someday. Seeing highly qualified postdocs (e.g., K99/R00 awards, great publication records, DEI and outreach work) unable to get faculty jobs is very discouraging since I think the main goal of many postdocs is to become competitive for a faculty position.

Existing NIH policies, programs, or resources

Expanding multi-year funding, both by giving more awards such as F32s or K99s to more postdocs, and by incorporating this into PI's grants. I am not sure what is typical, but having multi-year positions for postdocs incorporated into things like R01 budgets would be helpful, and incentivizing PI's to invest in the training of an individual postdoc. I have had a positive postdoc experience so far, largely because my PI has been supportive, has found ways to fund me and keep me in the lab past my original 1 year contract,

and is generally invested in training me and supporting my career. Some PIs are just better about this than others, but I think if R01s and other major grants were structured to incentivize this kind of longer term commitment to training an individual postdoc, it would improve the postdoc experience for a lot of people. Also, increasing postdoc pay and providing benefits such as parental leave and funding for childcare, for both postdocs on fellowships and being funded through their PI's grants.

Proven or promising external resources or approaches

Not sure

Response 1857

Perspectives on the postdoc roles and responsibilities

I strongly believe that postdoc position should be eliminated. People are underpaid and overworked. Less than 1% of postdocs have chance to get academic position, meaning that majority of postdocs will enter industry. Industry does not see postdoc position as work experience, resulting in low position. Same person entering in industry after graduation will spend same years as postdoc, but actually having job experience, also being paid as worker, not "trainee" . So, someone who graduated and went to industry will have chance in 5 years to be a labhead, while someone graduated same time, but spent 5 years being postdoc, will only have junior position. This is extremely unfair

Fundamental issues and challenges

Stop calling this position "trainee" and pay well. Postdocs are working late into night, weekends, also working on the computer in the evenings at home. Postdocs are main driving force for academic research and should be seen and appreciated as workers, not trainees

Existing NIH policies, programs, or resources

Response 1858

Perspectives on the postdoc roles and responsibilities

Postdoctoral fellows are responsible for a research project. That responsibility includes working jointly with the PI on experimental design, carrying out experiments, interpreting data, and writing manuscripts (and fellowship applications). Senior postdocs may also take on responsibility for training undergraduates and graduate students. Most importantly, the postdoc should invest 100% of themselves into research. Without that intrinsic motivation and drive for discovery, successful transition to an academic or industry research position is unlikely.

Fundamental issues and challenges

Postdoctoral training is just that—training. It is not a career path unto itself. My responsibility as a mentor is to provide in-depth interaction and feedback related to the postdoc's chosen area of research. I always tell potential trainees "It is not my job to respect your boundaries; it is my job to help you push past them." Unfortunately recent NIH policy changes has made that approach more difficult.

As an African-American female faculty member, I am routinely viewed through the 'loud Black woman' lens, including by trainees. The change in policy surrounding 'bullying' sent shivers down my spine. Accusations of 'bullying' can be valid, especially in the context of racial and sexual harassment. However, 'bullying' is also an allegation frequently thrown at faculty who are perceived incompetent due to racial and gender stereotypes. Issues of this importance should not be left to university HR departments, but that is what NIH has effectively done.

Existing NIH policies, programs, or resources

Postdocs deserve to be paid a living wage, especially in parts of the country with higher cost of living. But with the ever-increasing salary recommendations, and expansion of postdoctoral benefits packages,

something has to give. A faculty member with a modular R01 in 2008 (when I started my postdoc) could hire (3) postdocs, while I would be unable to hire more than 1 on a modular budget today. NIH should increase the amount of a modular budget and/or require that universities subsidize benefits (that exceed recommended NRSA stipend levels) from indirect costs.

Proven or promising external resources or approaches

As I see it, NIH has created (2) major points of contention between postdocs and their potential mentors. First, the increase in postdoc stipends and benefits is coming from the same pot of money (direct costs) as research funding. As a result, faculty are forced to choose between supporting a postdoc's leave of absence or maintaining progress on NIH-funded research. This is unsustainable, and universities should offset certain expenses from indirect costs. The second issue primarily affects underrepresented and female faculty; namely, the increasing weight given to trainee sensitivities places us at increased risk of career-ending accusations of 'bullying.' This issue cannot be left to HR departments and university administrators. The standard of evidence for non-sexual, non-racial harassment and bullying should be much higher to avoid spurious allegations.

Response 1859

Perspectives on the postdoc roles and responsibilities

While the postdoc is theoretically a training position, I view it more as a "Scientist" position. I think its interesting to ask what it means to be a trainee vs. a scientist. There will be some amount of learning in any new position, whether one is a trainee or not (ie, new methods, new analyses, etc). So what makes the postdoc position a training position, vs. a scientist position? I do not feel like a trainee even though I am doing many new things in my postdoc. I haven't felt like a trainee since mid-PhD. While I do learn new things, the foundational knowledge/skills that I use are not new. The fact that most scientific research in this country is performed by "trainees" is really telling—that should be an oxymoron. I'm not sure what it would take to turn the postdoc position back into a training position. Probably to shorten the PhD and postdoc periods. But to do that, the 'bar' for completion of each of those phases would need to be lowered (which would make sense! The current bar is too high and results in people being beyond the training period when they graduate & are postdocs). That seems very difficult though—it seems that the 'bar' at each stage is set by the 'bar' at the next higher stage, so then PhD and postdoc training is heavily influenced by how difficult it is to get grants, and get faculty positions. (Of course it is much much less difficult to get industry positions, which is great. And in fact, when I was in grad school, students who were only interested in industry positions were 'enabled' to graduate earlier since everyone knew that they didn't need such glitzy papers to be successful in their chosen path)

Fundamental issues and challenges

The main issue with recruitment, retention, and quality of life for postdoctoral "trainees" in academic research is the fact that we are paid very very poorly relative to our level of education and life stage. Sure, some postdocs work way too many hours, but if they were compensated appropriately that wouldn't be too bad. Why would someone enter a job that is expected to last 5-6 years with a salary that they probably cannot afford a moderately nice place to live, childcare, travel somewhere cool every now and then, when they could easily get a job that DOES enable them to do those things? Sure there are issues with bad mentorship and exploitation, but again, the PRIMARY issue that everyone likes to ignore is that postdocs are not paid well. (And called 'trainees' on top of that, despite often being the people that really drive the research forward). If my partner didn't have a job making lots of money, I probably would strongly consider leaving my postdoc soon, now that I have a kid and will need to pay 3/4 or more of my stipend for her childcare. Imagine if I was a single parent! It would be LITERALLY impossible. Of course, the NIH will need to get more money from congress to fix this problem, or the total number of postdocs will need to significantly decrease. Both seem unlikely, but I think those are the only real solutions here.

Existing NIH policies, programs, or resources

Pay postdocs more money. Thats the main thing. I could go on about other resources that could be helpful for mentorship, reporting bad advisors, enabling collaboration, etc etc. But the thing that will have the largest impact on the current and future lives of postdocs will be to make more money.

Proven or promising external resources or approaches

One thing I will say that has been excellent about my postdoc is that I have had 1-2 research assistants. Therefore I have my own mini-lab within the lab. This has provided me with valuable experience in mentorship and management. These are important skills for leading a lab that most postdocs don't get any experience with. I think postdocs should be required to have experience with mentorship, management, budgeting, fundraising, and other skills that are essential for their next position. This would also help turn the postdoc period back into a training period.

Response 1860

Perspectives on the postdoc roles and responsibilities

Postdoctoral positions are a mixed bag. I love having protected time to do work that is meaningful to me, have opportunities that I might otherwise be unable to take advantage of (that are paid for!), and have the flexibility of an academic schedule. I also have access to a series of amazing mentors, who will go above and beyond to make sure I get the experiences I need to reach my future goals. However, it seems like postdoctoral positions have become a necessary evil for most anyone graduating in my discipline with a Ph.D, especially if you want to pursue an academic position of any kind. While postdoctoral positions can be wonderful training opportunities, and allow fellows to gain skills they might not have gained during their doctoral training, it kind of feels like postdocs are a bit of a holding pattern. It feels like it's delaying being a "real" adult for a bit longer, and that general attitude makes it easy to devalue postdocs.

One major issue I have is the perspective of postdocs as still being "trainees." While post-docs are still getting additional training, they are not "trainees," at least in the same sense as graduate students are trainees. Postdoctoral positions are often viewed as Grad School 2.0, and as such funders, PIs, and other supervisors believe they can treat postdocs as unfairly as graduate students are treated. Postdocs are not treated as adults with jobs, but as students who should be grateful to have the opportunities that they have and should be expected to be compensated less in the name of "experience." While postdocs are often temporary training positions, it would be great to see the culture surrounding postdocs are trainess, who can be devalued and mistreated, change.

Fundamental issues and challenges

Financial challenges are absolutely the most fundamental issue for postdoctoral fellows. In many places, the standard salary of ~ $55k is not enough to live with a decent quality of life, much less begin to save to pay off debt or purchase a house. Especially with the skyrocketing inflation and landlords raising rents to astronomical levels, it's becoming harder and harder to live. I cannot stress how much being paid more can help in reducing stress, increasing quality of life, and improving work quality. Once you have that burden of "can I afford groceries this month?" off your shoulders, amazingly, you can focus on doing quality science and working to improve our society.

Postdocs are grown adults with Ph.Ds, NOT students. While post-docs may still be "training" to some extent, it is unreasonable and belittling to expect these highly trained scientists should accept less compensation in the name of training, or that they should just suck it up and live with four other roommates to just survive. Many people I know have put off reaching traditional life milestones, such as buying a home, getting married, or having children, because they simply cannot afford it. People pursue Ph.Ds for better opportunities and better pay, and to not receive adequate compesation after years of toil is ridiculous.

Moreover, lowballing post-docs on their salaries makes it okay for university departments to lowball faculty members on their salaries. After all, once you've been paid so little, any increase seems like a massive improvement (even if the improvement still isn't sufficient). The NIH has the power to set new standards for postdoctoral pay and training, and be at the forefront of improving the quality of life for all academics.

Existing NIH policies, programs, or resources

Make it easier for folks to access loan repayment. People have taken out hundreds of thousands of dollars in pursuit of a degree they thought would make them an adequate salary, only to find that academia and other corporations are not paying them what they are worth.

Proven or promising external resources or approaches

No response

Response 1861

Perspectives on the postdoc roles and responsibilities

An academic postdoc is a transition and training period to prepare PhDs for one of several types of career outcomes: academic, industry, government, or many others. It should be calibrated to best meet the goals and needs of the postdoc and the lab. For those bound for academia, the goal should be to build an independent research program and build a CV necessary for the job market. For those who have different ultimate goals, they may want to build skills in management, writing, particular marketable skills, etc. There needs to be a detailed discussion between the postdoc and PI to figure this out.

Fundamental issues and challenges

The low pay rate is a huge issue, especially in locations with high costs of living and/or for postdocs with childcare costs. Even for motivated trainees, it is often financially prohibitive to pursue a postdoc unless they can rely on the financial stability of family. These issues have become even more exacerbated during times of high inflation, when postdoc pay has not remotely kept pace with rising costs nationwide. Moreover, many postdocs are geographically restricted due to family obligations, dual-career complications, or the expansion of laws restricting the rights of women, minorities, and LGBT scientists in many parts of the country, so the option to move out of expensive regions is not available to everyone.

A second fundamental issue is the lack of career stability for postdocs. While this is intended to be a transition period, postdocs often have high uncertainty over whether/how long their funding will continue. Given the degree of randomness in the job market for academia and other fields, postdocs frequently 'time out' and have to pursue non-scientific careers merely because they didn't have an additional year of funding. This is represents a huge loss of training and talent.

Existing NIH policies, programs, or resources

Most importantly: increase the NIH minimum rates for postdoc compensation (and increase grant or fellowship budgets to accommodate this change). Many institutions use these rates as default postdoc salaries, and it is difficult to impossible to argue with HR or with NIH study section to justify raising postdoc salaries on a case-by-case basis. Ideally this increase should be tied to nationwide inflation rates and/or local costs of living to ensure keeping pace in the future.

Second, it would be great if NIH made a year-long fellowship specifically to support postdocs while they are on the job market, academic or otherwise. These job searches take up an enormous amount of time, during which little research can be done. But they are essential for postdoc retention in the scientific community long term, and should therefore be supported.

Third, a more ambitious change would be to adjust NIH rules to change where postdoc funding comes from, switching from the majority of postdocs paid by R01s to a majority being paid from training grants or fellowships. By tying the funding to the postdoc and allowing the money to move with them, this would give them more stability, more opportunity to move labs if their PI is exploitative, etc.

Proven or promising external resources or approaches

No response

Response 1862

Perspectives on the postdoc roles and responsibilities

Postdoctoral positions in US lost any appeal to me over the 4 years of my PhD. I am an international student from Europe and prior to coming for PhD I anticipated doing at least one post doc here in the states. Not anymore. Seeing scientists with doctoral degrees and years of postgrad experience being called trainees and paid 50k for the enormous amount of work they do is simply ridiculous. I am also aware that almost no americans are interested in these positions anymore. us postdoc is becoming low paid position for foreigners in which they are very likely to be exploited (tied by work permit and lack of finances). I will not put myswlf in that position. The US taxpayer money that was spent on my PhD will likely go to waste.

Fundamental issues and challenges

See previous comment. No 30+ yo with PhD wants to be underpaid, called a trainee and required to move around the country with 0 financial contribution from the institution. Also, what is the path for posdocs that wont become professors?

Existing NIH policies, programs, or resources

Pay for relocation, pay competitive salaries, more respect. People in waste management make more money than postdocs. also, no other industry calls people trainees for decades.

Proven or promising external resources or approaches

Honestly everyone in academia is making jokes about your little survey with comments like "lol, they KNOW what is the problem" . You look like you will do anything else rather than pay money and give respect.

Response 1863

Perspectives on the postdoc roles and responsibilities

The postdoctoral position is one that helps an early career clinician scientist/scientist obtain a faculty position. They are able to train with a mentor, lab or program that provides insights and experience into faculty positions and best ways to obtain funding (NIH, industry, etc.). You also begin to become a more independent researcher, and the time can help you decide the correct career path. Postdocs are also highly educated and trained and provide important services/duties for their labs or departments (whether clinical, clinical research, basic science, etc. responsibilities), and it is often done at a lower cost because we are not yet permanent faculty members.

Fundamental issues and challenges

The low salary is the number one issue (to me) for recruitment, retention, and overall quality of life. I understand it is a training position but ~$54,000 is not enough support for a doctoral level position; it also makes it difficult to support a family if the postdoc has children/dependents. This salary is just above my institution's salary for a research coordinator, which I find to be unacceptable given my education and level of training.

Existing NIH policies, programs, or resources

There should be more emphasis on how to obtain external funding since that is how faculty members keep their jobs in "soft money" positions. It would also be helpful if there were other avenues for early career funding, outside of the K99/K23 routine, since it is difficult to secure that funding. The funding in general at NIH seems more difficult to secure, based on anecdotal information I've received from other colleagues and mentors at my institution. This experience/information has made me consider positions outside of academia so I can start my career and make a good salary. I also don't agree with the payback policy that a postdoc must payback their stipend if they don't go into an academic position. There are many factors that contribute to a job decision and some of these may be out of the postdoc's control (e.g., securing funding for a K23; their department's funding, etc.). It is not fair to penalize someone for wanting to make a decent living, or if they decide to change their career plans (away from academia) to best support their wellbeing.

Proven or promising external resources or approaches

I'm not sure of helpful external resources.

Response 1864

Perspectives on the postdoc roles and responsibilities

The postdoctoral position should be a temporary, transitional role that bridges the gap between graduate school and a first career position. It should be a training position, with a focus on learning appropriate skills for the desired future career. It should not be a 'cheaper' version of a research scientist with full-time research responsibilities and very limited training resources.

Fundamental issues and challenges

Postdoctoral positions are billed as 'training' positions, but often the only training is work experience. However, similar to graduate students, the 'training' status of postdoctoral researches is used to justify working conditions that would otherwise be unacceptable. Salaries are below what most graduates with an undergraduate degree command, much less someone with a doctorate. Retirement benefits are typically non-existent. Long hours and limited time off (incl weekends) are common. In other fields, work experience for new graduates is gathered in a fully compensated entry-level position. Postdoctoral researchers should either be compensated according to the value they unquestionably bring to the research enterprise, or receive legitimate training as part of their position that is not just work experience and the occasional seminar. Regardless of all of this, postdoctoral salaries need to be adjusted for cost of living, and protections should be introduced to prevent exploitation of postdocs who depend on their mentor's recommendation, and possibly visa support. Limits on hours or overtime pay and minimum PTO should be considered.

Existing NIH policies, programs, or resources

See also above. Protections for postdoctoral researchers from exploitative PIs. Improved benefits. Cost-of-living adjustments. Limits on worked hours. True training requirements.

Proven or promising external resources or approaches

Unions help

Response 1865

Perspectives on the postdoc roles and responsibilities

Developing projects, organizing lab, training students and postdocs, disseminating data, research

Fundamental issues and challenges

Pay is less than half of what someone with a PhD can make in the industry. At [redacted for anonymity], it's impossible to pay for daycare and live as a postdoc.

Existing NIH policies, programs, or resources

Cover daycare costs, increase salary

Proven or promising external resources or approaches

No response

Response 1866

Perspectives on the postdoc roles and responsibilities

Academic postdocs are the primary workforce driving the most challenging research projects in the US. Postdocs design, execute, and analyze experiments, as well as organize data in presentable forms to write grants and manuscripts. They also train grad students and technicians. In short, they work both on and off the bench. Additionally, international postdocs are required to perform a lot of paperwork that relates to their visa to continue to have valid work status.

Fundamental issues and challenges

First is poor pay. Academic postdocs find it very difficult to maintain their basic expenses, and it compounds manyfold if they have a family. Second, is affordable childcare options. Third, is lack of mentoring when it comes to pursuing their future goals.

Existing NIH policies, programs, or resources

NIH needs to come up with policies that ensure better pay of the postdocs across the US. Secondly, dedicated mentoring programs for postdocs who are looking for a career in academia.

Proven or promising external resources or approaches

No response

Response 1867

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

1. Not enough financial support for trainees (e.g., funding for research coordinators/assistants, my K23 only covers 1/3 of a RAs salary).
2. Some trainees do not have extra time allocated for their research.

Existing NIH policies, programs, or resources

1. Each of the institutes should standardize support for K trainees (e.g. they range from 3-5 years, research support ranges from $25,000-$50,000/yr)

Proven or promising external resources or approaches

1. Free grant writing courses.
2. Free manuscript preparation courses.

Response 1868

Perspectives on the postdoc roles and responsibilities

I view my postdoc years as protected time to launch a career as an independent investigator. I am in a T32 funded position and have been able to use my postdoc years to

1. Focus on publishing my dissertation research,
2. Develop and write grant applications,
3. Support ongoing research through mentored research projects, and
4. Collect pilot/formative data for future research projects. This protected time has been enormously helpful, especially in having dedicated time for grant development and writing.

Fundamental issues and challenges

The primary challenge is salary. While the NIH provides minimum guidelines, my institution strictly adheres to them and offers no negotiation in that. Even when applying for other grants, for example the K99 which funds up to $100K in salary, my institution would only let me budget based on the NIH postdoc salary guidelines. Compared to industry and other fields, these salaries are simply not competitive and this alone has made me consider exploring non-academic careers. The student loan pause over the last few years was one of the only reasons that I was able to live somewhat comfortably with this salary.

Existing NIH policies, programs, or resources

Consider shortened timelines for applying for grants like the K99 or K22. The time to review made planning for these submissions difficult and significantly more stressful in conjunction with having to simultaneously start a job search in the event that the grant was not funded. Moreover, given that it may take several submission rounds until these grants are funded one might end up staying in a low paying postdoctoral position for longer than necessary as many institutions seem to expect one of these grants to even be considered for a faculty position. Had this been my situation, I almost certainly would have begun to apply for jobs outside of academia.

Additionally, consider making changes to the LRP program so that it is easier for postdocs to apply. I was able to apply this year, but would have loved to be able to previously. Student loans combined with low salary are a big challenge for many postdocs and the eligibility for the LRP and materials needed make it difficult to competitively apply for the award in the first year of a postdoc position (unless you are at the same institution where you completed your doctoral work).

Proven or promising external resources or approaches

No response

Response 1869

Perspectives on the postdoc roles and responsibilities

As a current postdoctoral researcher, I view the postdoc position as essential to my career progression, not because I could not be successful in an academic position immediately after completing my doctoral studies, but because the academic system is designed to support the established researchers rather than building for the future with supporting early-career researchers. I view the role of an academic postdoc as being biased towards the privileged US Citizen. I am privileged enough to be able to float in this transitional, temporary, and insecure position for a few years, but these conditions are eliminating many highly-skilled, highly-motivated scholars from pursuing research careers in academia. What should be a great opportunity to elevate research training through a structured path to independence, is filled with uncertainty, rising costs, and yet another costly transition to a new position.

Fundamental issues and challenges

The educational system has lost sight of its primary role: education. Academic institutions are now run as businesses where profits must increase and the majority of those profits must go to the elite few who sit atop its hierarchical structure (e.g., university presidents, football coaches, other male-dominated positions).

Almost all of these responses will likely discuss salaries not being representative of someone with a PhD, which I agree with, so I will focus on other problems. Cost of living differs vastly by area of the country, as well as by family status. As a father with two children, I can't live in an apartment with five other people to make rent affordable. Moving is also expensive and restrictive, yet there is no accounting of moving expenses in the transition to a postdoc position.

In addition to funding mechanisms being severely limited, most are also exclusive to US Citizens. Non-US citizens not being eligible for career training/fellowship/development awards is a poor system for building good scientists generating good science. Non-US citizens already have immensely greater costs with visa and travel requirements that restricting their ability to receive training and conduct research is making an already difficult, transitory time of life more complicated. NIH has perpetuated a negative stereotype of non-US Citizen scholars not contributing to society by making these important people ineligible for most funding mechanisms.

Existing NIH policies, programs, or resources

To control the PIs who manipulate and abuse postdocs through excessive workloads and unreasonable expectations, whether intentionally or unintentionally, PIs who accept postdocs into their labs should be monitored and reviewed. Are the PIs providing adequate meeting time with postdocs? Are PI's expecting reasonable working hours? Are the PIs helping postdocs transition into their careers or holding them back for their own benefits? If the PIs reviews are poor, should this PI be allowed to continue to accept postdocs? It is unreasonable for trainees to have to protect themselves under these power imbalances and conflicts of interest.

To encourage participation in training experiences, additional funds and/or waived expenses should be considered. Conference registration fees could be waived. Publications costs could be waived. Manuscript reviews could be paid. If there are additional students in the lab, mentoring efforts could be paid. These are valuable training experiences for postdocs who are filling a trainee role.

Proven or promising external resources or approaches

No response

Response 1870

Perspectives on the postdoc roles and responsibilities

The role of a postdoc varies too greatly. Some labs treat postdocs as independent researchers and expect them to get 100% of their own funding. Some treat them like they're still a graduate student and only "let" them work on the PI's R01. Some are somewhere in-between, which is how it should be in my opinion.

Fundamental issues and challenges

Money and work/life balance are the two biggest issues. The only real reasons I considered leaving academia were lack of support for postpartum (8 week maternity leave is shameful) and not making sufficient money to justify staying. It was REALLY hard to justify staying in such a low paying position when I had children to pay for. I know that many postdocs are in their peak childbearing years (if not beyond it thanks to grad school) and this is a huge concern for almost all of my friends and colleagues.

Existing NIH policies, programs, or resources

Extend parental leave (and extend the clock on grants dependent on time from graduation accordingly) and raise the minimum salary. In addition to minimum pay scales, there should be minimum requirements for additional benefits (healthcare, dental, parental leave, etc)

Proven or promising external resources or approaches

provide strong, mandatory verbiage in job contracts for postdocs funded from NIH grants around the required mentoring for a postdoc (I know most people wont use it still, but if its mandated that a PI help students with job application materials, protect 30% of time for their independent projects, etc then at least some will care).

Response 1871

Perspectives on the postdoc roles and responsibilities

Training position that needs the space to experiment with riskier and newer problems that will allow the postdoc to carve out a niche for themselves.

Fundamental issues and challenges

Postdoc salaries are not competitive with what the industry can offer. Just increasing postdoc and graduate student salary is not a solution if it is not accompanied with increases in grant budgets. Good quality postdocs often tend to chose very senior and established labs causing a bias of a lot of postdocs in just a few labs and no postdocs in all other labs. I do not think it is a bad thing for grad students and postdocs increasingly choosing industry vs academic positions, since that is proportional to the academic jobs available. However, in the face of a shrinking workforce, it is important to revisit what the expectations of productivity should be.

Existing NIH policies, programs, or resources

Grant mechanisms for riskier postdoc research projects. And postdocs who choose to join new PI labs should not be penalized for their courage and boldness when submitting fellowship applications if they have other institutional support and mentoring available. International postdocs working in US labs should be eligible for NIH postdoc fellowships. Excluding them is to remove 3/4ths of the actual academic postdoc pool and creates a huge financial burden on labs running on single R01 budgets.

Proven or promising external resources or approaches

No response

Response 1872

Perspectives on the postdoc roles and responsibilities

A postdoc is for training in a new field (3 year maximum) different than your PhD. It is not an extension of a PhD in the same field for >3 years. Responsibilities include training, conducting research, mentorship, and potentially teaching.

Fundamental issues and challenges

I cannot stress this enough--PAY POSTDOCS A WAGE COMPENSATORY WITH THEIR MARKET VALUE. And I mean retirement, maternity leave, health insurance, life insurance, dental insurance, vision insurance *in addition* to salary. Basic necessities for being a skilled worker in the US!! So many of my colleagues are rejecting a career in academia or a postdoc (myself included) because of this. Many PIs would also love to do this but are prevented by the current NIH salary caps when budgeting in grant applications.

Existing NIH policies, programs, or resources

Respectfully, I don't work for the NIH so I won't do your work for you :)

Proven or promising external resources or approaches

Respectfully, I don't work for the NIH so I won't do your work for you :)

Response 1873

Perspectives on the postdoc roles and responsibilities

The role of the academic postdoc is to provide semi-autonomous experience for a scientist to learn how to strategize and execute a coherent line of inquiry that will lead to actionable (that is, publishable) data symbolizing a meaningful contribution to science.

Fundamental issues and challenges

The goals, as outline above, are not explicitly stated with clear goals, objective, and timelines. Therefore, it seems more of a "black box" or "right of passage" that is successfully completed by those in well-funded laboratories. In addition, the life of a young investigator is often fraught with not enough research money, not enough administrative support (such as the availability of project management), makes the prospect of the finish line not particularly enticing.

Existing NIH policies, programs, or resources

1. Increase the salary of postdoctoral students
2. Do not call them "students" but rather something on a pre-professional track. An equivalent to medicine's "resident". It is an apprenticeship like a residency.
3. Clarify the skills that will be obtained. These are skills that are felt to be necessary lead a successful laboratory and lead a successful line of research inquiry.
4. Provide program management support for early faculty.
5. Increase the salary for young investigators/assistant professors
6. Provide information/guidance on industry: what industry scientists do, how to collaborate, how to recognize the benefits associated with academic/gov't institutions.
7. Encourage institutions to add courses on budgets and program management and make them required.

Proven or promising external resources or approaches

1. Increase the salary of postdoctoral students
2. Do not call them "students" but rather something on a pre-professional track. An equivalent to medicine's "resident". It is an apprenticeship like a residency.
3. Clarify the skills that will be obtained. These are skills that are felt to be necessary lead a successful laboratory and lead a successful line of research inquiry.
4. Provide program management support for early faculty.
5. Increase the salary for young investigators/assistant professors
6. Provide information/guidance on industry: what industry scientists do, how to collaborate, how to recognize the benefits associated with academic/gov't institutions.
7. Encourage institutions to add courses on budgets and program management and make them required.

Response 1874

Perspectives on the postdoc roles and responsibilities

I see this to be a pathway to becoming an independent researcher. Essentially going through intense training.

Fundamental issues and challenges

Single most important problem these days is the salary. People are not interested in taking the jobs when they see the offer letters and what they could get in industry.

Existing NIH policies, programs, or resources

Minimum postdoc salaries must be increased otherwise the system will most certainly fall. People are loosing interest in taking academic positions just because of meager salary. Even if the salaries aren't exactly competitive with the industry there must be a fair increase every year considering the inflation and cost of living. If this is not fixed we as academicians are doing an injustice to our system.

Proven or promising external resources or approaches

Having an unclear career path. What after postdoc is a big question to everyone. Some aren't prepared to write grants forever. Some students I know think that applying for grants essentially is scientific begging. This attitude must change and it can only be done from the top level.

Response 1875

Perspectives on the postdoc roles and responsibilities

Postdoctoral position help me to understand the research in depth and at the same time it allows me to enter scientific community.

Fundamental issues and challenges

The main fundamentals of inhibiting the retention in academic research is not paying enough wages according to current situation.

Existing NIH policies, programs, or resources

Existing NIH system is good enough for the programs and resources at some extent.

Proven or promising external resources or approaches

No response

Response 1876

Perspectives on the postdoc roles and responsibilities

As a postdoc, you aim to acquire and solidify skills that you will need as an independent investigator. Thus, you will likely have to invest a good deal of time into learning and not necessarily into data collection.

Fundamental issues and challenges

The postdoc salary is a major issue for retention. Many people leave postdoc positions for industry positions since this is often the phase of life when families are being started and money can become tight (true of men and women).

Existing NIH policies, programs, or resources

Extend K99 eligibility to allow experiments centered around slow models (e.g., genetically engineered mouse models, patient samples) to produce the necessary compelling data. This extension would also give the trainee more time to learn some of the skills necessary better increase their independence (e.g., learn to code) or develop tools needed to study their models.

Proven or promising external resources or approaches

No response

Response 1877

Perspectives on the postdoc roles and responsibilities

This postdoctoral position was intended for me to obtain experience with treatment and developmentally-oriented research. However, I have found it to be that I am running a project without a leader because the

PIs do not know how to conduct the analyses (whereas I do) and are too busy with other grants they have. I feel that I am getting paid miserably (despite being an adult and having a longstanding history of being paid horribly as a graduate student) while working hard and providing significant intellectual contribution to a project that I will have no significant acknowledgment for on my CV, while my PIs (whose salaries are bloated and spend their time on activities outside of this grant) get all the credit.

Fundamental issues and challenges

You are paying adults (who have been underpaid throughout their early careers as graduate students) below the national median income, during a time of economic insecurity and exponential increases in inflation. Postdoc positions do not feel like they are providing job or economic security. I feel like I am overworked, underpaid, and undervalued. The research enterprise takes advantage of how little it pays junior investigators. And you wonder why historically disadvantaged and minoritized groups aren't better represented in academia.

Existing NIH policies, programs, or resources

Pay your postdocs a minimum of 70,000 per year. Postdocs who are part of grants should be formally recognized in NIH grant repositories to avoid PIs getting credit/reputational benefits for their grants.

Proven or promising external resources or approaches

I cannot emphasize enough how important it is to pay us a respectable salary.

Response 1878

Perspectives on the postdoc roles and responsibilities

Manage projects and perform experiments with little assistance and constant pressure.

Fundamental issues and challenges

Low salary, poor work-life balance, low career trajectory and perpetual "trainee status" used to justify poor benefits (including retirement) and indefinite length.

Existing NIH policies, programs, or resources

Trash the postdoc status and mandate actual jobs with competitive salaries. Form a national union for labor rights.

Proven or promising external resources or approaches

MANDATE LABOR REFORMS.

Response 1879

Perspectives on the postdoc roles and responsibilities

Training and step to be an early investigator

Fundamental issues and challenges

Salary, few chances to continue in the area

Existing NIH policies, programs, or resources

Training for other important functions as an early investigator and professor

Proven or promising external resources or approaches

Mentoring, Better recruitment

Response 1880

Perspectives on the postdoc roles and responsibilities

I view the postdoctoral fellowship as a means to facilitate a transition into independence. The postdoctoral fellowship has allowed me to develop my own line of research while still having the support and infrastructure of a mentor. This time period also allows for further refinement of skills that will be needed to ensure independence at the next career stage. Such as grantsmanship, mentorship of other students and postdocs in the lab, oversight of research projects (implementation, data collection and analysis), and productivity through both presentations and manuscripts.

Fundamental issues and challenges

What I have found most challenging about being a postdoc is twofold. First and foremost, it is extremely challenging to be a postdoc from a financial standpoint. We often serve a large role in helping to maintain labs and it doesn't feel like the pay is commensurate with our experience or value. Beyond the salary, this is an extremely important period of transition when we need to be attending conferences for professional development and networking. My NIH grant, while I am grateful for the funding, only comes with $1000/yr for conference travel and this is barely enough to cover the cost of one conference. Typically, a PI would be able to apply for multiple grants to help offset some of these costs, but as a postdoc you are a bit limited in your effort (especially if you are on a fellowship that provides 75% protected time). I have had to pay thousands of dollars out of pocket to attend conferences which has furthered the financial strain. The second challenge of being a postdoc is feeling like you don't really have community or protections. We are in a weird transition zone where we aren't quite faculty but also aren't grad students anymore and it feels like at a institution level at least, there is uncertainty as to where we fit in. For example, I have a NIH grant where I am PI but at my institution, I am technically cannot be listed as a PI on my own grant and my mentor must do so. Overall, it just feels like we are underpaid and undervalued and it is hard to stay motivated when this is the case.

Existing NIH policies, programs, or resources

As mentioned, I have a NIH fellowship and while I am not sure how all fellowships work, this one in particular only helps cover $4000 in research costs and $1000 in travel per year. Yet, I feel the expectations of the grant was to have a highly rigorous project and training plan. This is hard to accomplish without adequate resources and supports for research. I think the existing fellowship programs should be closely examined to understand if more support can be given to those of us at this career stage. Even for those of us being supported by a mentor, it is difficult to ask them to cover all of the necessary costs that come with doing research at this level. Given that some of the K training grants at the early faculty level cover significantly more, it doesn't make sense that there is such a wide discrepancy between the support offered at that level and one step removed (postdoc level).

Proven or promising external resources or approaches

Something that has been helpful for the fellowship grant I am currently on is that we have monthly peer group meetings with other individuals that have the same grant. It has been tremendously helpful for fitting in and for having an inbuilt peer support system to discuss some of these issues and shortcomings and troubleshoot solutions. Not sure if this is a part of all of NIHs existing programs, but I think having more opportunities to build out these support networks (especially in person opportunities) is tremendously helpful for morale and to not feel so isolated and alone as a postdoc.

Response 1881

Perspectives on the postdoc roles and responsibilities

The postdoc position is one of training. It's in a weird limbo between being a fresh graduate but not quite experienced enough to be a faculty member. It should be a time of immense growth where a person is exposed to all sorts of new techniques, concepts and professional networks.

Fundamental issues and challenges

PIs disguising handing off responsibilities as "training" and loading a postdoc with so many responsibilities they barely have time to breathe.

Existing NIH policies, programs, or resources

Strict limits on what a postdoc can and cannot do e.g. not allowed to ghost write peer reviews (postdoc must receive credit), the number of students a postdoc is tasked to supervise, the amount of teaching or course development they are supposed to do etc

Proven or promising external resources or approaches

Mentoring. Having access to a senior PI that is not the postdoc's primary PI would be helpful.

Response 1882

Perspectives on the postdoc roles and responsibilities

I personally view it as an extension of graduate training, with more responsibilities but less structure, and the potential to one day apply for academic positions if the postdoctoral work goes well.

Fundamental issues and challenges

Compensation and the limited career opportunities following a postdoctoral position, which places you at risk of huge losses in potential earnings during the postdoctoral period with limited hope of eventual payoff.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

Increased emphasis and acceptance of non-academic tracks.

Response 1883

Perspectives on the postdoc roles and responsibilities

I feel I have many responsibilities and I do enjoy the work and challenges, but I do not think I am fairly compensated for my work. I have many friends working less hours for higher salaries in other fields. I have considered leaving academia for this exact reason.

Fundamental issues and challenges

I think the culture of science still isn't the most welcoming to non-white males, which could absolutely improve. I've encountered multiple older professors who don't seem to value DEI initiatives that younger generations are leading. I also think the main currency in academia is still publications and teaching/mentoring or outreach is second rate.

Existing NIH policies, programs, or resources

Increased salaries! I know my skillset is worth more than what I am paid.

Proven or promising external resources or approaches

No response

Response 1884

Perspectives on the postdoc roles and responsibilities

An academic postdoc is a period of additional experience and training. Time to produce publications in an additional area of research separate from these of predoctoral training. Responsibilities include producing data for the PI, supporting graduate and undergraduate students, and developing their own research ideas.

Fundamental issues and challenges

Inadequate salaries and no retirement benefits are the biggest challenges that make this trajectory unappealing. Having no financial stability is a huge stressor that reduces overall quality of life and progress.

Existing NIH policies, programs, or resources

Raising the national standards of pay for postdocs.

Proven or promising external resources or approaches

No response

Response 1885

Perspectives on the postdoc roles and responsibilities

Postdoctoral positions seem like required positions the long term goal of working in academia and/or as a professor, but does not seem to guarantee a position in academic. Being an academic postdoc seems like a lonely position in labs without other postdocs. Postdocs also do not have the social structure of classes with other graduate students or responsibilities that bring faculty members together. I'm not sure what responsibilities postdocs have, other than advancing the research efforts of their lab's PI, for slightly more benefits than a graduate student but still not much.

Fundamental issues and challenges

In a way, the academic postdoc position seems to have a serious PR issue. It doesn't seem like a net positive benefit for a graduate student as people may need multiple postdocs before getting an academic position, and people are older or have families but continue to earn few benefits for an unequal amount of work and effort. There are better financial and work-life balance opportunities in other sectors outside of academic research, so those who are able to do postdocs for academic research tend to have the privilege of a more financially stable partner or family members.

Existing NIH policies, programs, or resources

NIH does not seem to support my research field, as language research was removed from the NIDCD's strategic plan. If large federal organizations de-incentivize future career pathways like what has already transpired, I don't feel like academia or postdoctoral positions are welcoming for me. As a member of multiple minority groups and a researcher without financial privilege, I don't feel incentivized by the NIH to make multiple sacrifices for the chance at a few postdoc positions and meager benefits, in addition to the future uphill battle for an academic position if I am to pursue a postdoc and academic research career.

Proven or promising external resources or approaches

Improving the number of postdoctoral positions and work benefits, as well as offering more financial support for institutions to increase PhD student stipends and offer sustained support.

Response 1886

Perspectives on the postdoc roles and responsibilities

An academic post doc is a training position and the time should be spent learning and growing in preparation for an independent career.

Fundamental issues and challenges

Being a post doc feels like sitting in the waiting room between finishing a PhD and securing a faculty job. More and more people are getting PhDs, and there are fewer and fewer continuing academic jobs, so the waiting lines are getting longer. During my post doc interviews, I was told a typical post doc is now 4-5 years. To continue being a scientist, we need to secure independent funding or an academic job, and both require a solid letter from our post doc mentor. This sets up an environment where the mentor can exploit the post doc, using the post doc's time and talent to complete the mentor's projects and mentor our mentor's students, at the expense of the post docs training progression. We are told to prioritize our mentor's agenda above our own career progression. Enduring this environment may have been worth it in the past, when a post doc was 2 years and then you could go into a flexible and autonomous long term position. Nowadays, it just means taking less pay and being undervalued for an ever-increasing number of years with dwindling job prospects. This is not trivial and has a massive impact on wellbeing. Post docs are postponing their lives (not having children, not buying a house, not starting to save for retirement, having to move every few years away from family and friends).

Existing NIH policies, programs, or resources

5 years of guaranteed salary and benefits for each post doc that is not tied to a specific lab.

Proven or promising external resources or approaches

No response

Response 1887

Perspectives on the postdoc roles and responsibilities

Transitory step to an academic faculty position or the industry.

Gain new skills and expand knowledge.

Opportunity to make new collaborations.

Advance research.

Fundamental issues and challenges

High competition: Competition with peers who have established research programs in the US, particularly in positions at good universities.

Life instability because the contract is annually, particularly when there is a family and kids.

Time runs out to build a robust research program and advance an academic career.

Existing NIH policies, programs, or resources

I do not have enough knowledge to answer this question.

Proven or promising external resources or approaches

I do not have enough knowledge to answer this question.

Response 1888

Perspectives on the postdoc roles and responsibilities

Transition to faculty position while training in the science and techniques.

Fundamental issues and challenges

Very poor salary. Should be at least 50% more. Lack of retirement plan benefits.

Existing NIH policies, programs, or resources

The academic industry follows NIH standard for postdoc salary. If NiH raises the standard, the academia will follow.

Proven or promising external resources or approaches

No response

Response 1889

Perspectives on the postdoc roles and responsibilities

The postdoc position should not exist. Period. Many humanities PhDs secure faculty positions after graduate school. So should we. The postdoc to PI track at some unis are nice but I was never aware of any as a grad student. Never.

The postdoc position is set up for PIs to create abusive, toxic environments that perpetuate favoritism and gaslighting.

When colleagues say that their postdoc years were the best of their lives I often feel like I am living in an alternate universe looking in in a more evolved and harmonious one than my own.

Because the postdoc years SHOULD be the best time of you career. You don't have a thesis to tame, classes to take or teach. All you get to do is research, write papers and grants. I mean that's the best—in theory—but hardly in practice.

Fundamental issues and challenges

Toxic PIs, low pay, unrealistic expectations. I had a PI that fired me because I didn't learn and master ex vivo slice electrophysiology (from start to generating publishable date) in 4 weeks. It takes most people 6 months—1 year. The rig was 85% built and there was no one in the lab to train me.

Another toxic PI constantly compared me to a fellow postdoc in the lab. This person had done their PhD in the lab and was in the lab as a postdoc for about two years when I arrived. The PI would ask me why I didn't have as much data as the other postdoc and that this person was so efficient, productive and otherwise great. It got to a point that during my meetings with the PI they talked more about the other postdoc than my projects and ideas.

Existing NIH policies, programs, or resources

Get rid of the postdoc position! No amount of stringent policies will make toxic PIs shape up and act nice. No amount. It'll be easier to navigate these difficult people through being fellow faculty members that I have to be on a committee with or who are just one vote in a tenure and promotions committee. No research, monetary or any other ties that bind our sole academic fate to theirs would be awesome.

Proven or promising external resources or approaches

Abolish the postdoc position. Even postdoc affairs offices are mainly populated with faculty who, at the end of the day, look out for each other and not postdocs. Even unions preserve the viability of the union and not the postdoc person.

Response 1890

Perspectives on the postdoc roles and responsibilities

The postdoctoral position to me is a chance to gain more independence as a researcher before obtaining a faculty position. It should be a protected time to get grants in the pipeline while working on active research projects that can help establish a research portfolio. Its also an important time for mentorship and finding one's path in research.

Fundamental issues and challenges

As someone entering the postdoctoral search, salary and benefits are the main issue. Coming out of a doctoral program, I can go into industry and immediately make double what is being offered to me with the postdoctoral salary. This is paired with a second issue, that some PIs take advantage of the postdoctoral role and do not protect time for the postdoctoral fellows to write their own grants and establish themselves separately. Thus, some postdocs I've observed are doing the same amount of work as those in industry and being paid half. I think third, I would say perceived quality of life of postdocs varies by field and institution, but some postdocs do not feel they have sufficient work life balance, especially since this fellowship is meant to be a training opportunity. They often feel like they can't rest and have to keep publishing or keep studies going because otherwise they will not find successful faculty positions. Lastly, I have briefly heard a concern about the number of faculty positions and this may deter people from taking postdoctoral fellowships.

Existing NIH policies, programs, or resources

Unfortunately, I'm apprehensive about regulations to grant documents or NIH stipulations that ultimately come down to the PI or Institution being diligent. What the NIH can do is increased salary stipend and introduce regulations protecting time off to have a family or for medical reasons.

Proven or promising external resources or approaches

No response

Response 1891

Perspectives on the postdoc roles and responsibilities

I have always viewed the academic postdoc by its traditional definition as "a temporary and defined period of advanced training designed to prepare an individual for an independent research career." A postdoc should be building independence and intellectual rigor that would allow them to run a research group, usually (not always) in academia or industry. Doctoral level scientists who wish to pursue research-related careers (editing, policy, etc.) can benefit from postdoctoral training, but these individuals would be best served to limit the number of years spent in postdoctoral fellowships.

Fundamental issues and challenges

Its become widely understood by prospective undergraduates and graduate students that the quality of life and career outlook for doctoral students and, particularly, for postdoctoral fellows is low due to a number of factors, including: long hours, low stipends, no retirement, widespread poor mentorship, and unpleasant work environments. The central problem is the lack of viable positions at the end of the postdoc: the very purpose of the postdoc position (research independence) isn't supported by the job market.

Existing NIH policies, programs, or resources

Policies that work: funding opportunities for early funding stage investigators; funding flexibility for life circumstances (parenthood, illness, COVID delays on research); policies that attempt to achieve pay parity and equity. Training grants that require a detailed mentoring plan and environment (schools exaggerate the quality of their training environments). I want to add one thing here: NIH has passed some very well-meaning policies and requirements on research grants, training grants, etc. but academic institutions do not always take them seriously and they DO look for ways to cheat and game the system, and I have seen first-hand a willingness of sr. academic admin and faculty to not value their postdocs (I worked in academic postdoc admin; I saw it with my own eyes.) If there is a decline in postdoc numbers, it's in no small part due to the the environment and values these schools have built their research labor force upon.

Proven or promising external resources or approaches

The mentoring role of the PI should be better. No one should be doing a postdoc without retirement benefits--and certainly not for 5 or 8 years. If the job market doesn't need this many postdocs, maybe the "perceived decrease" [we need more real data on this observation] isn't a bad thing. I have consistently observed a significant number of postdocs not actually working as trainees, but rather as "staff" fulfilling the scientific mission of the PI. Perhaps re-envisioning the composition of the biomedical workforce is the better way: provide more opportunities to be professional staff scientists with retirement benefits--this would perhaps be a more honest and ethical position for many "trainees" who are in reality receiving no training or mentoring from their PIs anyway.

Response 1892

Perspectives on the postdoc roles and responsibilities

The postdoctoral position is the final phase of training in becoming an independent investigator/lab leader. It is a ~5 year position for a highly qualified person to perform full-time lab research while also gaining training in mentorship, teaching, and grant writing. This is often work that takes >40 hours per week yet is among the most poorly paid per level of qualification and work/effort. In order to retain and train the next generation of independent investigators, postdoc salaries and benefits need to increase significantly, or we will lose them to other careers. Postdoc-level research is also what keeps current labs afloat and full of exciting and new science. Without the postdoc workforce, current scientific research will inevitably decline. This is highly undesirable.

Fundamental issues and challenges

Stipends are too low; the majority of graduate students in my lab are looking at industry for their next step because the postdoc route seems too poorly paid. Quality of life for postdocs is too low, especially in major cities where costs of living are ever increasing. I recently had a postdoc candidate turn down my offer to work in my lab because she was worried about the high cost of living in the DC metro area.

Existing NIH policies, programs, or resources

increased stipends; more flexible timelines and visa rules

Proven or promising external resources or approaches

look at the benefits and working environment perks and benefits offered in the private sector for PhD-level scientists.

Response 1893

Perspectives on the postdoc roles and responsibilities

My job requires proficiencies in three computational languages, manuscript preparation, applying for funding, mentoring students, conferences and training, and guest lecturing. With this diverse job description post-docs are GROSSLY underpaid. In addition, I have to beg to get work-related costs paid and reimbursed. When I have discussions with my mentor, he also complains that PIs don't get paid a lot of money, but they are getting paid over 2x more than us. Postdoctoral positions are a cemented step toward becoming a PI with the promise of intellectual freedom. However, most people are finding this position is NOT worth it. It's one of the largest abuses in the system.

Fundamental issues and challenges

Post-docs are SO UNDERVALUED. As a highly skilled bioinformatician, I get paid less than my spouse who is a kindergarten teacher (which is a field also underpaid). Post-docs make less than graduate students per hour and don't have tuition remission. My institution does not contribute to retirement, and my medical/dental/benefits are five times more expensive than as a graduate student. Institutions are trying to employ post-docs for cheap labor, and people are finally realizing it. Thus, most people are skipping post-docs or trying to get out as soon as possible. Comparable positions are 80k-125k while I'm being paid 54k.

Existing NIH policies, programs, or resources

The pay is ridiculous. I was told I couldn't negotiate my salary because the medical school goes by the NIH pay scale. There is no federal standard for or retirement benefits.

Proven or promising external resources or approaches

No response

Response 1894

Perspectives on the postdoc roles and responsibilities

The postdoctoral position is one where you gain independence for an independent research career in academia or industry. It is a unique period where you are not solely responsible for your salary support, yet have the resources of an entire lab.

Fundamental issues and challenges

The major issue is salary caps and inability to supplement trainee incomes with grants. For example, NRSA stipend should be able to supplemented from other NIH grant sources, not strictly sundries. In order to recruit and retain, the salary structure must be figured out. In a high-cost city, the salary support is not enough, especially if you have a family. Due to this reason many, many leave academia for higher paying jobs.

Existing NIH policies, programs, or resources

As above, the major issue is salary caps and inability to supplement trainee incomes with grants. The total number of postdocs may decrease, however, they will be happier and healthier.

Proven or promising external resources or approaches

As above, limiting the sources of salary support and supplementation.

Response 1895

Perspectives on the postdoc roles and responsibilities

The postdoctoral fellowship is a path to independence in some way. This position should continue to teach you to ask scientific questions, draft manuscripts, design experiments, mentor, teach, and learn independently.

Fundamental issues and challenges

The current postdoctoral fellowship is not sustainable. The salary is pitiful and cannot sustain a family that many postdocs would like to have. This should NOT be a way for PIs to get cheap, well-trained lab labor. While I was doing my postdoctoral training, my research associates (first position right out of college) were making nearly as much as me after my 6 years of training in a PhD program. The postdoc program training scope is too narrow. Most are designed to train you for a career in academia as a PI and to make you feel guilty if you do not want this position. A postdoc should truly be to learn a new field or something entirely new instead of continuing in the same field as a PhD. More individuals should go to a staff scientist position if they would like to continue to do benchwork in a similar field to PhD. Currently, the length of a postdoc can be ridiculous. I did a four year post doc, but some people go as long as 6-8 years which is extensive for how poorly paid you are.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1896

Perspectives on the postdoc roles and responsibilities

Postdocs are the driving force behind the progression of science and technology. Postdocs train grads and undergrads, bring ideas to the lab, and design and execute experiments to address tough scientific questions.

Fundamental issues and challenges

After getting a Ph.D. postdoc still have to face a significant struggle in postdoctoral studies, and transition into the next level of his/her carrier. In the postdocs journey, not only a person but he/she must have a family and children with them, and the suffering will go all those as well. The Payscale is so insufficient that a postdoc can’t afford a proper meal and lifestyle despite doing a challenging job with a higher degree. A university or organization has to think about and ensure these issues that a postdoc has to face at the work level, mental level, and financial level in day-to-day life. Training is there but has to ensure the presence of postdocs must be there, many times PI don’t want them to attain talk series or training for the improvements of their carrier. NIH should bring Posdocs into the NIH or can come to the institute to train postdocs that are required for their carrier enhancement. Need to monitor, in university the Postdocs who are not working more, doing overtime and getting exhausted, and getting very less money and appreciation.

Existing NIH policies, programs, or resources

Resources have to increase, and programs and policies need to reach every postdoc.

Proven or promising external resources or approaches

Yes, Need to improve Postdoctoral recruitment, Training should reach every postdoc, work environment need to be monitored along with the universities or research institution. The work environment is critical, this should be taken care of very seriously. Highly ambitious PI and the very supporting institutional behavior of those PI can be the reason behind the exploitation of postdocs at the work and mental levels. Mentoring should be not only from the PI but also from the universities and Agencies like NIH that are needed for transition. If a postdoc enjoys his duties with full of pocket and fewer worries there will be job satisfaction

Response 1897

Perspectives on the postdoc roles and responsibilities

The postdoctoral position is a training period for researcher to earn more expertise for their future research career. This is a good chance for achieving new experiences and trainings.

Fundamental issues and challenges

The Fundamental issues and challenges inhibiting our experience include not-receiving proper information for training and opportunities, lack of support from our Principle Investigator for training, Low paid salary in an expensive city (such as , New York), lack of health insurance support from our university, lack of housing opportunities from the university, expensive rent in university housing, misuse of our visa category by our PI, micromanaging etc.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1898

Perspectives on the postdoc roles and responsibilities

Time to gain additional and new experiences and skillsets, consider different career paths (academic, industry), and learn more about processes for becoming a scientist or professor in academia. I view it as an additional transitional period that extends training beyond post-bac and PhD periods.

Fundamental issues and challenges

While quite variable, NIH postdoc pay is 1/8-2/3 of what could be earned from skipping a postdoc and retuning skills for industry or other non-academic careers that also provide significantly more stable career paths both in terms of career trajectory and stability of location. NIH postdoc salaries have increased below rates of inflation for decades. This is endemic throughout academia (i.e. salaries of assistant/associate/tenured professors), but salary prospects of professorship are still less than an entry level industry scientist positions (that do not require postdocs).

Anecdotal, but in my cohort, peers are exhausted with the amount of training before obtaining a stable, "real" job (e.g. 1-3 years postbac to build CV and research experience, 5-7 years PhD, 2-4 years postdoc). There is relatively little oversight of postdoc supervisors, resulting in variable work hours and expectations. Grant writing is increasingly complex with new additional requirements every 1-2 grant cycles, the review process seems too long, and awards are not guaranteed; the nature of risk aversion makes alternative careers more attractive.

Existing NIH policies, programs, or resources

Increased salaries for postdocs (150% of NIH scale at least) would make them more attractive. Expanding budgets for K awards that focus specifically on transitioning postdocs to next steps in research careers are important. Though K award rates are higher than R grants, those who might otherwise consider academic careers are going to weigh the gain/loss potential and lose interest if K awards rates are low. Trimming requirements on grant writing would also work to reduce administrative burden in submitting grant applications.

Unless budgets are radically expanded, reducing the size of PhD cohorts and postdoc programs may alleviate part of this issue. There are too few academic positions as-is, which may be increasing competition for these spots as the overall number of PhD holders continues to grow. Unless NIH increases salaries and opportunities for postdocs significantly, one option may be to reduce the number of postdoc positions and increase salaries.

Proven or promising external resources or approaches

Ongoing surveys of job satisfaction and mentoring for postdocs may be helpful to improve accountability of postdoc supervision, both for institutions and on a national scale.

Response 1899

Perspectives on the postdoc roles and responsibilities

The postdoctoral position should be a "stepping stone" between a PhD and full dependence in a faculty role. Given that there are few tenure-track faculty positions available these days, the academic postdoc should still offer training for careers outside of academia, in terms of leadership skills, career and professional development skills, budgeting and management experience.

Fundamental issues and challenges

The most important issue at hand is the lack of "livable" wages and benefits as a postdoc. Quality of life is naturally decreased when postdocs still have to worry about how to pay rent, child care, and medical bills (especially because ~$50-60k before taxes will not go a long way in a high cost of living area, which is also where many universities and institutions are located). Paired with this is the lack of benefits, including many postdoc positions not allowing you to save for retirement in a 403(b) or 401(k), and even if they do, most universities will not match their funds. This, paired with little to no savings during a PhD, sets back postdocs by around 10 years.

It may have previously been accepted that you will "suffer" a bit during your PhD and postdoc in order to land the "big" professor position. Given that these faculty openings are slim due to many reasons (university level decisions, inflation, etc), paired with the fact that starting assistant professor salaries are not even that much higher than a postdoc salary, this is not a sustainable model and is entirely different than, for example, a medical doctor's residency / fellowship training (where they make ~$60k for a few years but then make $200k+ in their first year after fellowship).

Additionally, there are few actual formal routes for training for postdocs. There is no requirement or incentive for a PI to formally mentor a postdoc. There are some opportunities through NIH for example for training workshops which are appreciated, but there is really a massive missing hole here where there is no onus on the PI to actually *train* a *trainee*.

Existing NIH policies, programs, or resources

The current NRSA F32 training grant is a great experience for postdocs to learn how to formally write their own mostly independent grant. However, there is another major missing link where many postdocs are then pulled off of their university funding to be funded by the F32, which means no benefits (I had to stop contributions to my 403b retirement due to going onto NRSA funding), and taxes are an entire mess with extremely little oversight or assistance.

More formal training resources should exist for postdocs, but also for PIs on how to mentor, would help this system survive. Unless there is a mandatory requirement at a PI level, PIs should not be able to hire postdocs. Often PIs are not made aware that postdocs on NRSA have to relinquish their retirement benefits and also have to pay estimated taxes individually on their stipend; education for PIs at what postdocs will "take on" should be made explicit anytime a PI agrees to sign on as a sponsor for a grant.

Given so few faculty positions available, maybe it is ok that postdocs are decreasing. Then, postdoc fellowship stipends should increase. An alternative is to provide postdocs on fellowships the option to use the institutional allowance as a flexible fund that can instead be used for stipend or to retain medical or retirement benefits.

There should a push to make a remote postdoc an option; with increasing computational positions this should be an option that NIH can advertise to allow postdocs the option to not uproot their lives yet again for a postdoc. NIH can help to not judge harshly a postdoc submitting an NRSA who has stayed at the same university or city, and instead encourage reviewers on study sections to view this as a positive to encourage a rich scientific *community*.

Proven or promising external resources or approaches

I truly think that one of the only things that will help improve postdoc recruitment and retention is to pay them more and ensure equal benefits that reflect what a person around, on average, age 26-35, would need to thrive (retirement, transportation, child care, salary, medical insurance) in any town or city across the country. The postdoc experience will not get better until this is improved upon. NIH can use examples from current universities raising postdoc salaries (I've seen closer to $75-80k raised at a few universities recently) to increase postdoc stipent funding, as well as to push the NIH to encourage universities also

individually raise their postdoc pay rate. Universities won't budge until NIH demands / requires that they do so.

Response 1900

Perspectives on the postdoc roles and responsibilities

The postdoc role is (what should be) a short term training position where individuals hone research interests, gain new technical skills, and establish a unique research program. While in theory the position is a training position, postdocs are the largest generators of data within research laboratories and bring a unique level of expertise and experience to labs. Postdocs serve as mentors to graduate students, undergraduates, and technicians—a role which spans issues related to technical understanding, foundational knowledge, navigating academia, and interpersonal relationships. As a postdoc, I am a key personnel and my contributions advance many parts of the lab.

Fundamental issues and challenges

There are many issues currently facing postdocs, particularly those living in larger cities. First, pay is abysmal. Not only is our pay not commensurate with similar jobs outside of academia, but also we are told that this position is simply a temporary training position that is going to set us up to be a faculty member at an R1. This is simply untrue. Postdocs are getting longer and the % of postdocs getting faculty positions is getting smaller. If you consider postdocs a training position for academia then the training program is a failure. Second, we have few to no benefits. At the [redacted for anonymity], we are offered no options for retirement, limited health insurance, no transportation/living/childcare allowance. When you consider the years that we are dedicating to this position, we are losing out on a huge amount in addition to our lack of pay. Many postdocs have to make the decision between starting a family and continuing their career. Third, we have no stability. The one year contract allows for PIs to have all of the power and international postdocs are particularly at risk. This structure reduces the chance that postdocs will speak up against unfair conditions as we are vulnerable to lose our job.

Existing NIH policies, programs, or resources

Increase the postdoc minimum pay! If universities are asking for more overhead due to the high cost of the area—then why aren't postdocs being compensated higher as well! Reduce overhead costs! Allocate funds toward postdocs—it is better to have fewer, better paid postdocs than the current structure.

Require benefits for postdoc be covered. GIVE US RETIREMENT! GIVE US HEALTH INSURANCE!

At many institutions, postdocs are punished for bringing in outside funding. This is insane.

Proven or promising external resources or approaches

No response

Response 1901

Perspectives on the postdoc roles and responsibilities

As a current MD-PhD student, the postdoctoral position presents an additional hurdle for establishing a R01 funded laboratory. While PSTP programs may equip certain physician-scientists to run their own lab, post-doc positions add additional time/experience to an already long path. The postdoc position is for future investigators to begin running independent research projects, while under the supervision and funding of a PI. While finding a postdoc position is not standardized, the specific roles/responsibilities of the post-docs I have worked with are even less standardized. At times, postdocs function as adjunct faculty (running independent projects under the PI's department), while at other times they function as glorified technicians/staff scientists (keeping the PI's projects moving forward).

Fundamental issues and challenges

From a MSTP perspective, time is the biggest challenge. It seems easier to begin a clinical practice at an academic medical center, then transition into basic science research (compared to a postdoc position). Additionally, finding an open postdoc position that will prepare me for the research I want to pursue with a PI who will give the right balance of independence and mentorship seems extremely challenging.

Existing NIH policies, programs, or resources

A physician-scientist oriented postdoc pathway would be incredibly valuable. Especially if it were focused on establishing a lab—like a dual postdoc/R01 position over 2-3 years.

No response

Response 1902

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

The salary level of postdoctoral fellows is way lower than what they deserve. A considerable number of postdoctoral fellows have families and children, and the extremely low wage income is inconsistent with their professional knowledge. Due to the pressure of living costs, quite a lot of them have given up their initial plan and then entered the industry. At the same time, more and more Ph.D. candidates no longer seek postdoctoral training programs, but directly entered the industry after graduation.

Existing NIH policies, programs, or resources

Response 1904

Perspectives on the postdoc roles and responsibilities

Make me more capable and to build up my ability to be a scientist.

Fundamental issues and challenges

The supervisor’s character and ability.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1905

Perspectives on the postdoc roles and responsibilities

An opportunity to explore new research fields and learn new techniques;

Develop skills (lab management, personnel recruitment and training etc.—these skills are very important but often neglected during Predoctoral training) and build connections (also very hard during graduate school) for an independent PI position;

Generate preliminary data for future research programs and possibly secure funding before transitioning to faculty (research funding mechanisms available to pre-doctoral students are way too few)

Fundamental issues and challenges

Salary and benefits are way below industrial positions and often times cannot cover basic living costs.

As a result, many PIs tend to forget that postdocs are seeking for training, but instead hire us as skilled technicians.

The nature of scientific research often prohibits postdocs to take vacations and requires us to work way overtime. But we are never compensated for the extra hours we have spent. We are paid for 40 hours a week but it is extremely rare to find a postdoc who do not spend over 50 hours per week. Further, many PIs do not allow or discourage long vacations, even if it does not exceed the number of vacation days allowed in our contract.

All these factors make postdocs not get enough respect or reward for the amount of time and effort we have spent in the past to earn our degree, nor does it match what we need to do to excel as a postdoc.

Even when we do sacrifice a lot of time for personal and family life, and give up on the potentially high salary we could have got if we were to take an industrial position, there are too few faculty position openings for us to transition to our next career stage. Many junior faculties nowadays have to spend almost 10 years as a postdoc/instructor to finally start their own lab.

Visa and political issues are also making it more and more difficult to hire international postdocs.

Existing NIH policies, programs, or resources

Make salary guidelines match the qualifications and efforts of postdocs—we have undergone many years of trainings and are working almost 24/7 to get our job done

Extramural and intramural postdocs should have the same salary/benefit guidelines

Increase the numbers of transitional grants like K99/R00

Set a new investigator Payline (like the current R01) for other NIH funding mechanisms

Proven or promising external resources or approaches

Many institutions have raised their minimal salary amount for postdocs. NIH should follow this trend and release new guidelines ASAP.

Response 1906

Perspectives on the postdoc roles and responsibilities

The Post doctoral training is an opportunity for me to do something different from what I did during my PhD. That’s the reason why I switched field from evolutionary genetics to long non coding RNA biology.

It also gives as the required training to get skilled for future prospects in academics or industry.

Fundamental issues and challenges

Following are the fundamental issues in my view:

1. Insufficient pay: the post docs all across the US have meager payment. It’s not sufficient enough tho sustain a family of two.
2. Mad rush for papers and not enough focus on skilled training.
3. Lack of opportunities in academics after finishing post doctoral training.

Existing NIH policies, programs, or resources

1. Pay structure: The pay should definitely be improved.
2. More focus on skilled training and mentorship.

Proven or promising external resources or approaches

No response

Response 1907

No response

Response 1908

Perspectives on the postdoc roles and responsibilities

1. Academic science—it's a workhorse of academic science, pursuing academic science projects
2. Training opportunity for scientists—it's an opportunity to train in a specific discipline of interest

Fundamental issues and challenges

1. Salary payment is severely below industry and almost poverty in certain locations—it's non-viable for some scientists w/ families, financial responsibilities etc

Existing NIH policies, programs, or resources

minimal salary policies from NIH were not followed during my postdoc years, despite being on NIH funded projects. enforcement of these policies or better awareness promotion for postdocs should be better.

Proven or promising external resources or approaches

funding for postdoc associations and postdoc groups within each institution is helpful for helping postdocs obtain better satisfaction with work environment.

Response 1909

Perspectives on the postdoc roles and responsibilities

I view a good postdoctoral position as a "PI with training wheels." It is a role with increased independence, in which I can demonstrate that I am capable of gaining funding and amassing publications while also designing, directing, and executing research, analyzing and visualizing data, and taking a leadership role in the lab, all while under the mentorship, supervision, and support of an existing lab head. It is also a chance to gain additional skill sets and expertise in technical and academic specialties, to improve "soft skills," and to broaden one's professional network across multiple institutions and possibly disciplines or fields.

As a postdoc at a different R1 than the one where I earned my PhD, I currently hold 2 simultaneous postdoctoral fellowships and an LRP award, and I have also been recognized for my teaching, mentorship,

and DEI-promoting activism. I presented at four conferences last year, and I am leading the production of 2 manuscripts at present, with more as a middle author. I am, by most metrics I am aware of, the kind of postdoc the NIH wants to keep in academia, and I would like to stay. However, I strongly believe that a postdoctoral position must be sustainable; it is not another trial to be endured while hoping for a professorship. If I had not found a like-minded postdoctoral mentor, I would not be here.

Fundamental issues and challenges

I am still in academia because:

a) I am interested in the research question, and enjoy the autonomy I found here,

b) My advisor has my career development in mind as well as her own success; she supports me regardless of whether or not I start my own lab, and her expectations for me are both clear and reasonable,

c) I like the location and I can afford (barely) to live here,

d) My lab-mates are good people and create a healthy, supportive environment where we can do good, rigorous, team-based science,

e) I am receiving professional development opportunities that help me grow in directions I want to, and

f) I am not planning on becoming pregnant or ever being able to buy my own house.

Many postdoctoral roles do not satisfy A-D, either because of a toxic environment or an unlivable stipend. PhD students spent our entire scientific careers being reminded that, in spite of our qualifications, we may not be able to find a professorial role. It therefore did not make sense to me to spend years of my life in an unpleasant environment, living hand-to-mouth, or with poor work-life balance, on the chance that I might land that role. Thus, I developed points A-D as hallmarks of a "good" role for myself. If I hadn't found a postdoctoral position that met those criteria, I would have left academia. I admit I was unaware as a grad student that point E would be important, but I got lucky. Point F gives me a measure of freedom and the ability to take a lower paying job; however, if I suddenly need to support family members, I will have to transition to industry (for the record, this is why you lose so many first-generation and/or female trainees).

Existing NIH policies, programs, or resources

The NIH IRACDA program (my primary fellowship) provides regular professional development opportunities (grant-writing workshops, teaching and mentoring workshops, an academic lab management and leadership symposium, public speaking workshops, etc.) as well as exposure to other professors and their labs, which broadens my professional network. Further, it offers a 'cohort' of incoming postdoctoral fellows not unlike those found in graduate school, which helps offset the isolation many postdocs feel. Finally, it offers four years of funding, meaning after getting this award I was able to focus on my research rather than worrying where my salary was going to come from.

The other key NIH program has been the NIH Loan Repayment Program, which helps me pay down my considerable undergraduate debt. I mentally consider this to be part of my income, meaning that my "bar" is set higher as far as salaries for industry jobs go, and I am less likely to leave.

Proven or promising external resources or approaches

This question is unclear. However, improving structure is frequently helpful, particularly to trainees from nontraditional backgrounds, as are various methods of cluster-hiring, such as those found at the graduate and faculty levels. Another key component of success as a postdoctoral fellow is a supportive mentor, yet we hear many stories of mentors that consider postdocs to be more like workhorses than colleagues. Having a secondary mentor to turn to (in the same way a graduate student has a committee) could improve working environments.

Finally, given that the NIH pays its own postdoctoral researchers well above their stated minimum, I assume they are aware that said salary minimum is woefully inadequate for professionals with advanced degrees in our late 20's or early 30's. This is particularly true given the lack of a geographical salary adjustment. As an illustration: a postdoc needs a higher salary to afford a 1-bedroom apartment in California or Massachusetts than in Wisconsin or Missouri.

However, given that increasing salaries would require increasing grant sizes, which may be unlikely, the NIH could also consider requiring grantee institutions to offer benefits, such as a certain amount of maternal leave, child/dependent-care, or paid time off (the UCs offer 24 days/year, plus sick and holiday, which is better than most American companies). Basically, if you're not going to offer a competitive salary, the job had better be really, really attractive for other reasons.

Response 1910

Perspectives on the postdoc roles and responsibilities

It is an opportunity to further strengthen our knowledge in the subject and gain expertise in data analysis, manuscript and grant writing. It should also provide a platform for us to mentor students and learn leadership skills

Fundamental issues and challenges

Delay in response from PIs hiring postdocs; salary paid and benefits for postdocs are reasonably low which makes people get into jobs than do postdocs.

Existing NIH policies, programs, or resources

Encouraging more postdocs to apply for career transition and broader training for career pathways. Also, a system for the international postdocs to continue or switch jobs, smoother visa renewal through NIH if possible

Proven or promising external resources or approaches

Need to improve recruitment and job satisfaction. Working environment would be dependent on the university and mentor. If more postdocs are hired, the work pressure comes down and they can focus on personal and career development.

Response 1911

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

No response

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1912

Perspectives on the postdoc roles and responsibilities

They are the power source and forms the frontline of breakthrough scientific discoveries.

Fundamental issues and challenges

Limited salary incomparable to what the industry pays makes recruiting and retaining talented postdocs difficult. And there is a big career barrier for tensioning from postdoc to the next academic level.

Existing NIH policies, programs, or resources

Elevate the salary cap for postdoc;

Elevate the funding cap for each NIH mechanism so that PIs have the room to pay postdoc more;

Provide more opportunities like K99/R00.

Proven or promising external resources or approaches

Not sure whether my personal thoughts are feasible or not, as I am not familiar with how NIH runs. But for the long-term in my opinion, NIH should try to convince Congress to allocate more resources to NIH.

Response 1913

Perspectives on the postdoc roles and responsibilities

A postdoctoral position is an opportunity to fill in potential training gaps left at the end of your doctoral program and to began forming a career plan as an independent investigator under expert guidance (i.e., when to apply for funding, publication and presentation goals).

Fundamental issues and challenges

Pay. Postdoctoral fellows are not paid well enough, especially in areas of the country with higher costs of living.

Existing NIH policies, programs, or resources

There really should be more opportunities for pre-doctoral international students to help fund their studies. Not necessarily expanding the current options, but providing a new option that is explicitly option for international pre-doctoral (and potentially post-doctoral) students who need experience competing for research and opportunities to fund their studies (reducing all potential need of student loans and alternative funding).

Proven or promising external resources or approaches

No response

Response 1914

Perspectives on the postdoc roles and responsibilities

First, let me give you the demographic of my perspective to contextualize my comments and give some weight to my responses. I just completed my postdoc a view months ago. I served in the role for 3 years. The first 6 months were in person and the next 2 and half years through COVID times. I was promoted after receiving a K award from an NIH institution. During my postdoc, I published 27 papers, 2 in Nature, and 7 others in top journals in my field (11 first authors). Given my ability to secure independent funding and publish effectively, I would say I am a recent example of a "successful postdoc perspective", though I know others could be more successful than I have been.

Given that background, I strongly feel that a postdoc position has three essential roles in a lab. First, postdocs are the engineers that make labs run. PI's typically have broader ideas about what to do, but manifesting their ideas almost always requires expertise in technical areas they have not been trained in. Second, Postdocs must develop their own careers. This means finding unique skills to leverage in applying for funding and making relationships with others outside of your lab, even though many PI's are loathe to allow you too much time outside the lab (note: my mentors were fantastic and this was never an issue for me). Third, postdocs are writers and editors. I spend more of my time dealing with journal and publishing than I do getting to use my Ph.D.

Finally, in all these things, postdocs are supposed to receive training. Unfortunately, given the explosion of technology and academia's slow growth toward complexity, hard skills training is typically from other postdocs, workshops, or the internet. PI's fill out more soft knowledge sets and networking.

Fundamental issues and challenges

I think the main issue is that there are better options for highly skilled individuals. I will break that down into three areas here and then below I will parallel those three areas with some potential solutions.

First and most obviously, pay. Postdocs do not make the same money as what anyone else would pay for a an advanced doctoral degree. In terms of specific barriers, pay equity rules and grant limitations still exist even when the money is there.

Second, the scope of projects in academia is becoming more limited. Industry positions can offer more data, adequate statistical power, protected time, and better equipment. Further, the main "scope" of

academia is publication, with many promising manuscripts getting drowned out in the sea of competitiveness, there is little time, resources, or samples to build a project that impacts the world.

Third, too much external control. I want to say it again, I had fantastic PI's. My PI's had very little influence over my projects after they went into review. They had very little influence over my K and how others in the department treated me. Let me illuminate this with experience, in order to handle the onslaught of comments the postdocs here have a saying: "assume your reviewers are going through a divorce". Given the massive uptick in publication expectancies in recent years, this mean that the perverse incentive to publish a lot of low quality work is running against constant non-constructive and toxic criticism from editors and peer-reviewers. Handling criticism is not the problem, the onslaught of criticism given by modern competitive standards is a drain on mental health. We are having trouble finding postdocs because we are literally chasing them out by refusing to change anything except incremental increases in our publishing requirements.

Existing NIH policies, programs, or resources

For NIH policies, we can address these three issues above in three ways.

First, pay postdocs more. You will hear it a lot but it is the number one thing you can do.

Second, expand the scope of postdoctoral training by encouraging more long term positions with adequate pay. For example, if someone is trying to create an animal colony but it will take 3 years instead of 2, let them but also increase their pay as they continue. Further, you could allow postdocs more time in their positions as long as the pay increases. If a postdoc has been working for 5 years in their position and they apply for funding to maintain an important line of work, let them. As long as the pay increases they can continue to collect data and focus on projects of higher scope. The end all of our careers does not need to be independence.

Third, expand training options to include broader networks of collaborators. Funding consortiums, animal breeding programs, and centers that employ postdocs is a necessary first step. Further, ensure that those centers have funds to send the postdocs to training and give them dedicated time to build the scientific pipelines they learn above, rather than force postdocs to focus on the next publication their entire career. I'll talk more about decentralization of academia in the next post, but this is how NIH has historically created projects of big scope with direct management of postdocs, if we also allow these positions to serve as feedback for postdocs, and we know the PI's receiving these funds are non-toxic, it can reduce the external pressure postdocs may feel.

Proven or promising external resources or approaches

So breaking from my nice structure above, there is really one thing that you need to do. Stop the narrow academic pipeline and create jobs outside the narrow scope of existing academic careers. Many scientific academic jobs are given little pay, respect, or job security, but in the modern scientific world they are completely necessary. For example, maintaining large scale studies or data like UKB or All of Us, or working on GWAS consortium as an analyst supporting PIs are incredibly important to maintain stable high impact biomedical work. Despite the skill sets needed and these jobs necessity the current academic system disincentivizes individuals from taking these jobs. Worse still, these jobs change hands frequently because we label postdoc as a low pay temporary career and do not give any opportunity for the work we have done on these projects to be long term, increasing error and time to train. Meanwhile, false positives propagate the field while a few PI's gorge their labs on the rotating door of postdocs to produce low quality work. So change the views of the types of careers that are good for science. Allow necessary jobs stability and adequate pay.

Finally, decentralizing academia means changing your standards of a "good scientist". Stop letting toxic peer reviewers and for profit journals decide what is good work. NIH should set its own standards, otherwise private interests will continue to decimate scientific goals. I had "academic success" in my postdoc. I never feel like I had scientific success or made a real breakthrough. I was constantly and almost daily frustrated by for profit interests and toxic personas. NIH has a responsibility to create an alternative, or others will see the writing on the wall and avoid a postdoc for the promises of another career.

Response 1915

Perspectives on the postdoc roles and responsibilities

Postdoc position gave me the opportunity to move to another country and challege myself in multiple aspect. I learnt to navigate a different system, I learnt different jobs.

Fundamental issues and challenges

The postdoc life is drastically unbalanced: very few days of vacation, which are often perceved as a reward for extra work instead of rights.

The uncertainty of the work, added to the visa related issues (hence mobility towars the homecountry, health care etc) and the rigitiy of the administrative machine, make impossible to pursue academic and personal goals without, unecessary and out of proportion, stress, that is not even matched by the salary. Specially compared to industry.

Moreover the tasks that are requested to postdoc often lie outside the jobs itself.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1916

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

Pay scales are low. Lack of benefits. Investigators tend to use postdocs as technical support rather than providing mentorship needed to get their trainees to the next stage of there career. Job opportunities in academia for new investigators having recently completed their postdoc are too few.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1917

Perspectives on the postdoc roles and responsibilities

Help needed to postdocs:

- To make clear instructions on requirements and opportunities to be promoted to a faculty position after postdoc.
- To increase postdoc salary, with increase of a yearly increase, too. Make it higher than of lab technicians.

Fundamental issues and challenges

- To help with employment of spouses of intnl postdocs (institution could hire them to technical jobs or provide short courses helping to find any job), since it is difficult to live on 1 postdoc salary only especially with kids.
- To allow to live in postdoc housing until the end of their postdocs.

Existing NIH policies, programs, or resources

- To provide more support for postdoc's families and children especially: fitness facility, extracurricular activities, sports.
- To make more events involving children of postdocs.

Proven or promising external resources or approaches

- To increase grant and promotional opportunities to non-resident international postdocs (w/o green card).
- To allow postdocs with both PhD and MD degrees to skip the instructor step and go straight to assistant professor position during promotion.
- To give opportunities to postdocs to earn more money, maybe give additional paid administrative, teaching assignments, etc.

Response 1918

Perspectives on the postdoc roles and responsibilities

Postdoc is a training-focused position that is equipping me with knowledge and skills. It is a stepping stone that is preparing me with a professional experience for a career in academia or industry. In particular, I hope to gain independence, and technical skills for a scientific career, where I hope to transfer the acquired new ideas and skills.

Fundamental issues and challenges

Family life is a major challenge for most postdoc, most of whom are of the age of starting families. Most postdoc positions lack family support systems. This is more complicated for international postdocs who have to leave their country to start a postdoc in a foreign country. They particularly find it difficult to relocate their dependents. Lack of family support also make it difficult for postdocs with children. The postdoc salary is not enough to sustain a family in a foreign country. Job uncertainty and also lack of job security hampers productivity as the postdocs are worried of their next move. The visa status and having to worry about visa renewal limits international postdocs mobility into areas where they might be resourceful. Female postdocs are worried that taking a gap like in the case of maternity leave would cause them to lag behind their male counterparts in terns of promotion and career progression.

Existing NIH policies, programs, or resources

Funding postdoc research in their own countries would help postdoc to continue their research while taking care of their families and dependents in their familiar environment. To achieve their goals, such postdocs would need access to funds.

Proven or promising external resources or approaches

Sandwich programs where postdocs would spend some time doing research in an international lab and some time in their home country can make a difference in post-doc retention. Assigning postdoc mentors in their area of specialization. Structured career progression for postdocs.

Response 1919

Perspectives on the postdoc roles and responsibilities

I think it is exciting opportunity to do challenging research

Fundamental issues and challenges

The quality of life is horrible. Long working hours with below poverty pay and no appreciation of the work we do. The credit card bills are rising as salary can't pay bills.

Existing NIH policies, programs, or resources

Increase the pay

Proven or promising external resources or approaches

More pay would solve most problems

Response 1920

Perspectives on the postdoc roles and responsibilities

Post-doctoral position for me a transition between grad school and an independent investigator role. It should allow me to show my skills as well as learn independently (or with minimal supervision). It should allow opportunities for grant submissions, publish papers and preliminary data that can help me get to the next step.

Fundamental issues and challenges

It is as simple as this;

1. Much greater working hours and low pay in academia.
2. People in post doc positions are usually in their prime to get married, have families, so both the pay scale and working hours work against balancing this for us
3. Industries have valued people with similar skills at 2-3x greater pay scale. Naturally they offer everything academia doesn't so people leave academia or opt for industry right after phd

Existing NIH policies, programs, or resources

1. Higher pay scale please!
2. Allowing PIs to offer greater salaries and helping them endure the cost
3. More early career grants/fellowship for pre-post docs
4. Making policies that discourage PIs to use pre and postdocs for years and years as cheap labor

Proven or promising external resources or approaches

Not sure about this. I am sorry all of the above mentioned will enhance postdoctoral training ecosystem.

One key answer to this is; increased salary!

Response 1921

Perspectives on the postdoc roles and responsibilities

In practice it is working for a professor doing their vision of your project. Overtime work, research only, no time for further career development

Fundamental issues and challenges

Low pay long hours short contracts NO preparation for non academic jobs

Pyramid scheme

Imbalance of power between employee and employer

Existing NIH policies, programs, or resources

Raised Minimum wage, two career tracks (academic vs industry) with two different expectations and contracts for each, award most individuals with salary grants, so there is flexibility in moving to different lab if incompatible or abusive relationship forms with mentor

Proven or promising external resources or approaches

Award individuals with grants that cover their salary and benefits so we have autonomy in moving around

Co-mentorship by non faculty who approves project as being in employees best interest

Response 1922

Perspectives on the postdoc roles and responsibilities

The academic postdoc is a necessary step of training to achieve an academic faculty position. It allows for development of research independence and training in several aspects necessary to run a successful academic research group, including research, time, and personnel management, expansion of laboratory techniques, mentoring, grant and manuscript writing, oral presentation, academic service, and networking. The postdoc allows for risk taking and learning under the support and safety net of established investigators, as well as time to establish a publication and funding record, preliminary data, and independent research direction.

Fundamental issues and challenges

Postdoctoral trainees are under considerable pressure to publish high impact manuscripts and attain independent funding in a relatively short amount of time. Postdocs, which typically range in age from late 20s to 40s, have already spent a considerable time gaining education and research training. They are often expected to move across the country (or world) multiple times between undergraduate training and faculty position. This can be a huge burden on those with partners and children, or who have other family obligations. This is especially difficult for international postdocs or postdocs coming from socioeconomically disadvantaged backgrounds. Aside from all the difficulties of moving, finding a partner a new job, and children new schools, there is also a huge financial burden. All aspects of the postdoc are financially burdensome. After receiving an incredibly small stipend throughout PhD training, most postdocs are unable to afford basic living expenses without financial support from a partner or having a roommate (and have high debt from student loans). Additionally, postdocs on training grants do not have taxes taken out of their paychecks (and are expected to pay estimated tax quarterly) and are not allowed to contribute to retirement (which puts them way behind in contributions). Additionally, postdocs are expected to maintain high research output for their mentors' projects while simultaneously developing an independent program, while balancing mentoring, teaching, and service activities and personal life (health and family obligations). Most postdocs work between 60-80 hours per week and are not appropriately compensated for the extra time. Many postdocs have to weigh career success against family success, and the lack of support for families during the postdoc causes many to put off or refrain from having children altogether. With postdocs in industry making substantially more money, it is no wonder academic postdocs are lacking.

Existing NIH policies, programs, or resources

Postdocs on training grants should be treated as employees when it comes to taxes and retirement contributions, so that taxes are appropriately being taken out of their paychecks and retirement contributions can begin as early as possible. Postdoc salary in academia should be equitable to industry postdoc positions and should take into consideration cost of living at each institution.

Proven or promising external resources or approaches

No response

Response 1923

Perspectives on the postdoc roles and responsibilities

The postdoctoral position serves as a transitional stage for aspiring principal investigators. It an opportunity to gain independence and demonstrate the ability to potentially lead novel research and manage a lab. Individuals with no aspirations to be principal investigators should not do a postdoc. If they want to stay in academia, they should transition directly into staff scientist positions. Of course this means more cost for the principal investigators.

Fundamental issues and challenges

Low and noncompetitive salary. I was only one of two individuals in my PhD cohort of around 20 who went on to do a postdoctoral fellowship. Compared to my PhD colleagues, my salary is extremely low. Additionally, compared to others with the same skill sets, particularly computational skill sets, my salary is also extremely low. As a URM and someone defined as coming from a 'Socioeconomic Disadvantaged' background using NIH criteria, I am aware of the cost of losing out on a large earning potential. This

makes it extremely difficult to continue staying within academia. I am not arguing that we should be paid the same as scientists in other industries, but we should be reasonably compensated.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

It would be interesting to determine the postdoctoral satisfication level between high and low earning postdocs.

Response 1924

Perspectives on the postdoc roles and responsibilities

Intermediate between grad student and supervisor. Lots of leadership roles relative to graduate school.

Fundamental issues and challenges

Low pay, no benefits such as retirement funding, treated as a staff scientist when it benefits the institution, but considered a trainee to reduce pay and benefits.

Existing NIH policies, programs, or resources

Add more funding of R01 grants, they need to slide upwards with inflation.

Proven or promising external resources or approaches

Add more funding of R01 grants, they need to slide upwards with inflation.

Response 1925

Perspectives on the postdoc roles and responsibilities

I see it as a bridge between the PhD and a full-time research position. I've assumed many responsibilities of a PI which include: mentoring students; managing the lab; designing experiments; analyzing data; writing manuscripts; and writing grants.

Fundamental issues and challenges

Where do I start. The pay is low. The benefits have not been great. Most critically, postdoc support seems geared for postdocs interested in the academic track, which is highly unattractive to me because it is not friendly to folks who need to be around their families and don't have generational wealth to rely on. I would appreciate more support for researchers interested in non-academic research. I've had to find many of these opportunities on my own through cold emails and extensive independent networking.

Existing NIH policies, programs, or resources

More support for non-academic researchers. Also higher pay to make postdoc positions competitive—most of the postdocs I know come from wealthy families, which exacerbates the income gap in academia.

Proven or promising external resources or approaches

No response

Response 1926

Perspectives on the postdoc roles and responsibilities

I viewed my time as a postdoc as a training step that would prepare me for an independent, tenure-track faculty position.

Fundamental issues and challenges

There are MANY challenges facing postdoctoral researchers, particularly those with families:

1. The pay is too low to support a family in many geographical areas.
2. There is poor support and oversight to ensure that we receive the training and support we need to transition to faculty.
3. There is an expectation that you will not have a healthy work/life balance, which makes it difficult to be psychologically healthy.
4. The career transition awards for late-stage postdoctoral fellows and research-track faculty are FAR too limited. How are we supposed to make the transition without funding? How are we supposed to get that funding if we had things that slowed our progress (e.g., parental leave and multiple postdoctoral positions)? Time allowances for parental leave are poor if present at all. There is no allowances if we had to leave our first postdoctoral position because it was unsuitable (e.g., lack of funding, lack of mentoring, discrimination, hostile work environment). These things happen all the time for postdocs, and we are punished for them. MDs have MANY more opportunities for career transition awards than PhDs, which further limits the advancement of PhD postdocs by giving MDs a double advantage for many faculty positions.
5. The issues stacked against us can make for an extremely frustrating, lonely time.
6. The lack of retirement benefits at many institutions during graduate school and postdoctoral training places an undue, lifelong burden on us.

Existing NIH policies, programs, or resources

1. Expand career transition awards for PhDs. Offer more of them across the timeline of training, not just early postdocs. There needs to be opportunities for K99/R00 funding for later-stage postdocs. The existing timeline does not work if you have ANY delay in progress due to family obligations or poor lab environment.
2. Having a formal mentoring committee for postdocs (like graduate students have) might help, especially if their mentor is not properly preparing and supporting their postdoc.
3. Improving resources and support for postdocs facing discrimination/harassment/hostile work environments.
4. Better support for postdocs with families: child care subsidies that actually make child care affordable, guaranteed parental leave (at least 3 months) with funding for technician support to prevent gaps in productivity, ways to ensure healthy work/life balance (e.g., allow postdocs to get funding for technicians to support their project).
5. Travel and registration awards for postdocs to attend scientific conferences. Many mentors are reluctant to pay, and so we have to pay out of pocket or skip these valuable networking opportunities entirely.
6. Improve postdoctoral salaries. We should not have to be impoverished to follow our careers. The myth of the scientist who devotes their entire life to science at the detriment to their financial stability needs to go away.

Proven or promising external resources or approaches

The [redacted for anonymity] has a postdoctoral union that has been working towards some of these things. Their efforts have helped postdocs but need to go much further.

Response 1927

Perspectives on the postdoc roles and responsibilities

The postdoc position was presented to me as a PhD student as the next necessary step toward obtaining a worthwhile faculty position. Now that I am a postdoc, I feel that the position was mischaracterized to me. I have fewer formal responsibilities but a much larger set of informal responsibilities, including learning new skills, networking, and managing things like healthcare and benefits. Furthermore, rather than having a “break” from academic stress, I feel as though I am now suffering from accumulated stress from graduate school.

On the surface, the postdoc position is meant to be a mentored training position where I expand my skillset as a researcher and contribute to meaningful research output. In practice, I have few opportunities

to pick up new skills while also attempting to publish as much work as possible in the very limited timeframe available to me.

Fundamental issues and challenges

Institutional support is either minimal or non-existent. The two postdoc office staff are overworked and unable to address even a fraction of postdoc concerns. There is no peer network either since most postdocs are so overworked that they are unable to engage socially. Our institution treats postdocs as pseudo-students or pseudo-staff, depending on what benefits the institution more. As such, we have no guidance for managing our benefits, no opportunities to pursue institutional funding for travel or research, and no opportunities to conduct our own research outside of our PIs' work. Furthermore, PIs are the ultimate decision-making figure for postdocs and have little guidance or oversight as to how they treat their postdocs. While some PIs are incredible and empathetic mentors, there are others that are actively harming their postdocs' career prospects and well-being. There is no recourse for postdocs either. Since the appointment is so short, any administrative action taken against a harmful PI will likely occur after the postdoc appointment. As such, postdocs are seen as disposable since "a new postdoc will always turn up".

Existing NIH policies, programs, or resources

The NIH needs to require institutions to develop oversight boards with federal regulatory connections that can systematically evaluate that institution's postdoc experiences, identify harmful PIs, recommend changes, and potentially ban a PI, department, and/or institution from recruiting postdocs due to problematic behavior.

Proven or promising external resources or approaches

The national postdoc association has great resources and recently published a report on the postdoc experience. [redacted for anonymity] postdoc office is also currently conducting research on the postdoc experience utilizing qualitative and quantitative methodologies that would be a useful template for broader research. [redacted for anonymity].

Response 1928

Perspectives on the postdoc roles and responsibilities

I see postdocs as an excellent opportunity that can potentially benefit both the trainee and senior investigators. It can benefit trainees in obvious ways—gaining access to senior investigators with skills to bring in funding, opportunities to publish using senior investigators' data, opportunities to network. Senior investigators can benefit by having extremely bright trainees bring in new energy and new ideas to their labs. But I feel it often turns out to benefit senior investigators more than the postdocs, who can be left feeling unsupported and trapped.

Fundamental issues and challenges

Postdocs can find themselves as "cheap labor", compelled to do work that benefits a senior investigator but not their own career progression, or being mistreated or harassed by a senior investigator. Because universities protect senior investigators who bring in significant funding, it is difficult for postdocs to refuse to do work that does not benefit their own career, or to make complaints about these investigators because postdocs likely need recommendations from the senior investigator, or may need their name to support their own applications for funding (e.g., as a mentor on a K application), or may need the senior investigator's data so they can build their publication record. When they do report mistreatment, it is often to other senior investigators who may not be willing to help the postdoc due to their own relationships with the perpetrator of the mistreatment. Postdocs can become trapped in a position with a senior investigator who is taking advantage of them or mistreating them in some way. Aside from the overwhelming amount of work many postdocs are required to do, this is the most stressful aspect of being a postdoc that I have observed among postdocs at my institution. I recently heard of a postdoc at my institution who turned down a K award because working with certain senior PIs was so problematic.

Existing NIH policies, programs, or resources

NIH policies should explicitly include bullying (e.g., forcing a postdoc to work unpaid/with no FTE on the investigator's project at the expense of the postdoc's own training plan). It is almost impossible for postdocs to feel comfortable in filing a complaint while they are still working under the problematic PI, as

once the university is notified of the complaint, it may be obvious to the PI who the complainant is, which can make the working situation even worse for the postdoc. NIH should institute a "exit interview" with all postdocs at the end of their training, which explicitly asks about bullying, harassment, and other ways the postdoc may have been taken advantage of.

Also, it takes so long between submission of a grant application and granting of awards that postdocs (and junior faculty) remain in a constant state of stress and uncertainty, sometimes spending a great deal of time resubmitting awards that are on the borderline just in case the first application doesn't get funded. The time between grant submission and award decision needs to be shortened.

Proven or promising external resources or approaches

Postdoc mentors who are on training grants funded by NIH may benefit from some sort of mentorship training that includes what NIH would see as appropriate/inappropriate behavior, e.g., it is appropriate for a postdoc to be doing work that helps them proceed towards their training goals, but it is misconduct to have them do unpaid/unacknowledged work on projects that do not align with training goals.

Perhaps an NIH hotline where postdocs could call or write and ask questions about situations in their postdocs anonymously might help NIH better see what issues are most problematic for postdocs, as right now in my experience, postdocs are suffering but scared to speak up about what is going on in their training experiences.

Support groups for postdocs would be very beneficial. Often they end up isolated in one lab without access to other postdocs, and they may think their experience is unique.

Response 1929

Perspectives on the postdoc roles and responsibilities

Postdocs are the backbone of academic research and the advancement of scientific research. One particularly crucial role that postdocs play is to bridge multidisciplinary collaborations between labs (e.g. from PhD lab to overlapping interests of postdoc lab)

Fundamental issues and challenges

- Postdocs who are awarded and accept NIH postdoc fellowships end up taking a financial blow to accept a NRSA award. For example in my scenario, I lost over $8,000 per year in health insurance and other benefits contributions from my institution when I accepted my F32. I was faced with the decision to pay $8,000 per year out of pocket or to decline this prestigious award that I believed would benefit my future career.
- I don't know the solution to this, its certainly a big problem and my scenario is not unique. Perhaps the NIH

Please, please, PLEASE require the institution to pay postdocs a MINIMUM of the published NIH NRSA stipend level as NRSA awardees. Do not decline a request for increase in salary to match the appropriate NRSA level based on the budget included at the time of submission of application. Our institutions will not input our salary to anything more than that which we currently have.

Existing NIH policies, programs, or resources

K99R00—childcare subsidy eligibility—I applaud the NIH for offering the $2500 childcare subsidy for postdoc fellows; however, as a K99R00 award recipient who is still in my postdoc fellowship training phase, I am ineligible to receive these childcare subsidies. Thus, my entire current NRSA level salary as a postdoc is going towards paying for childcare for my two children so that I can continue to work full time. Please help to bridge this gap for K99R00 postdoc award recipients by expanding the eligibility of childcare subsidies to include ALL NIH-funded postdoc fellows.

Proven or promising external resources or approaches

improve support for health insurance and childcare for postdoc fellows.

Response 1930

Perspectives on the postdoc roles and responsibilities

The postdoctoral position is an opportunity to gain additional scientific skills before starting an independent position, however, it seems necessary to have a high impact publication in order to secure a tenure track position. When working with mice such a project can take 5+ years making the post doc feel like another PhD project

Fundamental issues and challenges

Low pay has to be the single biggest factor. My classmates that went into industry following graduate school make at least 2x the salary I do. They can afford to buy homes and pay for childcare whereas I am putting off having children because I can't afford them right now. My institute provides no retirement contribution so not only am I making less money over my lifetime but I will also have to work longer because I will have less retirement funds

Existing NIH policies, programs, or resources

I was delighted to receive the NIH loan repayment program but unfortunately I had to turn it down because of the requirement to stay in a post doc position for two years or pay $50,000 penalty plus the money awarded back. When I initially applied for this program that seemed worth it but it was 9 months before I heard back on my application. In that time a parent was diagnosed with a fatal illness requiring medication that costs over $1500 per month. I needed to turn down the NIH LRP because I may need to switch career paths in the near future if my family needs financial help.

The NIH should also work with universities to make sure trainees receiving awards aren't penalized. My institute doesn't do this but some institutes reduce trainee benefits when they are on a fellowship.

I appreciate NIH fellowship institutional allowances, I don't know any other job where employees are required to provide their own lap top for work, without the NIH institutional allowance I would have had to buy a laptop out of pocket. Institutional allowances should be increased to match inflation. I also appreciate cohort-based fellowship programs, having that connection to other underrepresented minorities has been a life saver during my training

Proven or promising external resources or approaches

My institute pays me ~$5000 per year more because I received an outside fellowship. Putting the application for this fellowship together took many hours and this policy incentivizes post docs to take the time to apply and rewards us for being successful. Policies that don't allow post docs to make more than other post docs claim to be interested in maintaining equity but having the opportunity to be compensated more inspired me to work harder and makes me feel more valued. It is also worth it to consider if recruiting more postdocs is a valuable goal. What will these postdocs do after they finish their position? There aren't enough faculty positions for everyone. We need permanent positions and doing a post doc only to not receive a faculty position is not helpful for the trainee and causes long term financial hardship. It is clear that our academic system has come to rely on highly trained post docs to create the results labs publish and receive funding off of. We spend long hours in the lab for poor pay and poor benefits. We train graduate students and undergraduates and positively contribute to lab and institute environment but are often treated as disposable (e.g. my contract at my institute is at will so I could be fired at any moment and post docs only have access to specific health care plans that are worse than those available to other staff). Some ideas to improve working environment/ job satisfaction: higher salaries, opportunities for merit based raises, better benefits (e.g. retirement matching, improved mental health care access, child or elder care support), increased creation of permanent positions, more programs to fund research assistance for post docs, addressing racial funding disparities in NIH funding so we can see people who look like us be successful.

Response 1931

management for mobile clinics in sub Saharan east Africa to areas that are politically negreted,due to HIV AIDS, nepotism, tribalism, revenge for political royalists verses opposition communities

Fundamental issues and challenges

Kenya among several other universities in Africa use outdated colonial standards of education.People from poor families get it difficulty to be awarded post doctorate degrees.Even Busuries and grants are issued to communities that voted for ruling party.

Existing NIH policies, programs, or resources

Colonial regime killed herbal and traditional African experts despite their roles in promoting healthcare for centuries. Currently corruption is witnessed in universities . I submitted 20 different important drugs entitled Effective affordable natural traditional drugs during my physical oral interview before being recognized as a herbal Doctor in accordance with healthcare policies .Instead of indicating all my submitted 20 different drugs,they only mentioned six drugs in my research report.

Proven or promising external resources or approaches

The world health organization is not able to rescue the talented traditional African experts despite having controling about almost two hundred member countries. traditional African drug discovery practitioner do research without receing government funding. In 2020 December recently I was among 15 selected harbal experts interviewed by a team from Kenya medical research institute which was responsible for developing a vaccine for COVID-19. To my surprise.Each of us interviewed was only given Kenya shillings one thousand equivalent to $8 dollars for issuing discovered herbal drugs for COVID-19 treatment. Compared to several millions given to our country for COVID-19 research I strongly know that it was and is unfair in this modern world.

Response 1933

Perspectives on the postdoc roles and responsibilities

A Postdoc is about gaining skills and experience to help you advance to the next stage of your carer. Postdocs do essential research to advance science and/or medicine.

Fundamental issues and challenges

Conflict resolution. When a Postdoc is being taken advantage of by their supervisor or has a dispute with their supervisor there are very few resources available to help them resolve the dispute. The supervisor knows that their threat of leaving a negative letter of recommendation holds the Postdocs future in their hands. This environment is intentionally left this way by Universities to allow the abusive behavior to continue and to discourage Postdocs from raising conduct issues.

Full time employment. Many Postdoc employees are considered “temporary” employees or something similar. This is a weak excuse by universities to provide terrible benefits to postdocs. This often leads them to be excluded from certain services as they are not employees and not students or outright forgotten as upper administration does not know they exist.

Facilitate long term employment. Postdocs mostly move up to tenure track faculty or make a large change in carer. The ability to continue to grow as an academic researcher without jumping to tenure track faculty would be useful.

Pay them more. Postdocs are grossly underpaid for their skill level and hard work they put in. Also the old thinking of "suck it up and work hard now and you will be rewarded with a good job later" is becoming more and more untrue. Pay them for the work they are doing not the potential that maybe for a small percent of them it will lead to a great position

Fundamental issues and challenges

Funding of labs by R01 grants is leading to unhealthy competition between PIs and postdocs. Each project(/data from it) is a possibility to write an R01 grant for a PI/head of the lab. If a postdoc wants to get independent and e.g. write a K99/R00 with this data (generated by him/her) on his/her project, it leads to a situation where de facto, there is a conflict of interest over hundreds of thousands of dollars between the postdoc and PI/head of the lab, and this will not seldom result in PI not supporting or actively harming the postdoc (I have seen a situation like this). This is not only a great disadvantage for postdocs, but this also harms whole labs and science. Ambitious postdocs fighting for their right to achieve independence and keeping scientific ideas for themselves, but then finally leaving academia because of the lack of support, are a great loss of intellectual potential.

Existing NIH policies, programs, or resources

Introduce a special, exceptional possibility for postdocs to be Co-PI on R01, with their "separated part" (e.g. one of the Aims) having a K-similar aspect. Theoretically, postdocs at some institutions can be (Co)PIs on R grant applications, however, mostly, they don't get support for that. Making shared applications between mentor and postdoc attractive for both parties would strengthen the postdocs and science (because there will be more collaboration instead of competition between the researcher generations).

Proven or promising external resources or approaches

No response

Response 1935

Perspectives on the postdoc roles and responsibilities

A postdoc is an opportunity to gain more training in new scientific techniques, ideally mentoring students in the lab, and learning how to (further) write grants and run a lab.

It is a secondary training step before becoming a PI.

The time that a postdoc should last is extremely ambiguous and context dependent.

Fundamental issues and challenges

Salary is low given the amount of training and expertise postdocs have. At a time when some postdocs are considering starting their own families, low salaries put pressure on those to either leave academia to be able to support a family or to not have children given the lack of financial resources and time. This disproportionately affects women given the restrictions on age to conceive and bear children. This is part of the reason why retention of female postdocs is low, especially in academia.

On T32 slots for postdocs, there are no retirement benefits; this needs to be changed for multiple reasons, but specifically because given the stage of life many postdocs are at, it is not feasible to not be saving for retirement.

Right now, given the pandemic, there is a glut of eligible candidates for a limited number of professor positions, making the market the most competitive it has ever been.

Existing NIH policies, programs, or resources

The 4 year restriction for the K99-R00 is extremely difficult and only achievable in a best case scenario. Accomplishing writing a grant with preliminary data requires a supportive PI and science to go well and work (not always feasible, especially if you are in a wet lab and doing a lot of animal work). Writing this grant can sometimes be at odds with the goals the postdoc was hired to accomplish (doing the research on already funded grants from the PI), so that can limit time and resources. Furthermore, with a global pandemic, extensions, even still are needed as we recover from the major effects of shutting down laboratories for months at a time (which some labs enforced and others did not, so the perception that this extension is no longer applicable is inaccurate).

And again, if postdocs are debating to have families during this time, it essentially becomes a choice of generate data and write a grant or decrease your hours given the adjustment to having a newborn and forget about being able to submit this grant given the time restrictions, especially if you are a mom trying to breastfeed. I truly appreciate the 1 year extension that has been added. However, with the pandemic and giving birth, the time has not been enough. We have so much research documenting how important it is for the infant to have time with their parents in the first 3 years of life. Creating an environment that allows for healthier and better neurodevelopment of the infant, as well as several other beneficial outcomes for both parents and baby, is supposedly what the NIH is supposed to be all about. Let's provide the infrastructure to allow postdocs, especially females, to do academic research and have a family!

Proven or promising external resources or approaches

- Holding PI's accountable for training their postdocs and not just using them as workhorses.
- Incentivizing PI's to mentor their postdocs and support them in writing grants. Giving extensions to those postdocs who found themselves in a toxic lab environment and a PI who did not support writing a K99-R00 (or even F31 or F32's) because the research that needed to get done was what was already funded and left no time for someone else to pursue generating data for their own grant.

Response 1936

Perspectives on the postdoc roles and responsibilities

I saw my postdoc as an opportunity to train in new topics and techniques relative to my graduate work. Postdocs have many roles and responsibilities: produce novel research and prepare for a career as a scientist, supervise graduate students and lab technicians, assist the PI, and sometimes teaching.

Fundamental issues and challenges

Quality of life for a postdoc is generally pretty awful. I have not met a lot of happy postdocs. Pay is ridiculously low, many PIs are cruel and see postdocs as cheap skilled labor. Preparation for running one's own lab and getting an academic post is lacking. At least in my post (neuroscience) no one I knew got an academic post until they were a postdoc for 7 or 8 years. That is too long to be working 90 hours per week for 50k a year. As soon as I left my postdoc for industry my salary nearly doubled and I do not think that is unusual.

Existing NIH policies, programs, or resources

I was lucky enough to earn a NIH-NRSA during my postdoc. I think that program should incorporate more career development. All my PI cared about was that I collected data and analyzed it. THat fulfilled my grant obligations. If the NRSA training program was more broad and focused on all aspects of developing an academic career, it would be better. This may have changed since I completed my postdoc in 2016, but I am not certain. In addition, universities should be required to submit evidence of PI misconduct to the NIH. My postdoc PI was notorious for her mistreatment of postdocs and if the university had reported her she might not still be supervising unhappy postdocs.

Proven or promising external resources or approaches

Its simple. Postdocs should be paid more and PIs should be expected to treat them as humans that are there to learn, not provide cheap labor.

Response 1937

Perspectives on the postdoc roles and responsibilities

I view a post doc as an apprentice to the PI. Often working independently post docs learn to develop either their own research program, harnessing experimental, mentoring and writing skills. Alternatively those who do shorter post docs with the intention of leaving for industry use the position to learn new techniques and improve their scientific communication skills.

Fundamental issues and challenges

Post doctoral pay prohibits individuals who are not already in a financially privileged state from considering the position even if they originally wanted to stay in academia. Without a partner/spouse/family to assist with cost of living it is difficult to pay bills, student loan repayments, etc especially if you went straight from undergrad to grad school with no way of incurring savings. Unless post doctoral pay mirrors at of industry I understand who many leave academia after graduate school.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

More opportunities for structured post docs would be great. I am aware that there are some programs where a cohort comes in together and receives specific training in not only research but teaching. If there were options for a much more scaled back version of a graduate program where post docs have access to special seminars/training opportunities outside of just lab research based on various career interests I think that would appeal to a wider audience and attract more applicants

Response 1938

Perspectives on the postdoc roles and responsibilities

Speaking on behalf of [redacted for anonymity] certain aspects of an academic postdoc position should be flexible depending on the scientific needs and mentorship style of the PI. However, some aspects of a quality position should be uniform across labs and institutions. In particular, a post-doctoral position should always entail additional training that complements prior training and positions the post-doc to advance to a future career position, whether within academia or industry.

We are concerned that many current postdoc positions are limited in terms of career development. Examples include that of a "semi-permanent" staff scientist role or a laboratory manager leading multiple scientific projects. We observe that these positions support the PI's research agenda but do not facilitate a pathway to independence for the mentee.

We believe that an effective and quality postdoc position includes

a) an outline of scientific goals that enhances the postdoc's experience/expertise while simultaneously benefitting the PI,

b) a well-outlined career development plan that includes access and interaction with a diverse team of mentors [e.g., career coaches, content experts] and

c) a clear path toward independence in a timely manner.

PIs must demonstrate to the NIH that members in their laboratory deemed as "postdocs" are being trained as described above. Those who do not fit this definition of a postdoc (e.g., staff scientists) should be paid much higher than the NIH postdoc stipends. Currently, postdocs funded under T32s and F32s have training plans written in the grant, but there is no requirement for training plans for postdocs that are funded primarily from a PI's grant. With characteristics of a postdoc position better defined, qualified candidates will consider these positions more desirable as they pursue their career goals.

Fundamental issues and challenges

The primary challenge, especially in the San Francisco Bay area, is salary support. The cost of living (particularly in this area but for most urban regions in the US) is too high to permit a reasonable quality of life with a postdoc's salary. This leads qualified candidates to seek higher salaries (e.g., within industry) earlier in their careers, limiting the number of qualified candidates targeting careers within academia. We recommend that NIH salary scales for postdocs be adjusted country-wide based on the cost of living in a specific regional area. Accordingly, PI funding should be increased to accommodate postdoc salary increases. For example, the ceiling for modular R01 budgets has not changed in over 2 decades and should be increased.

As for increasing the quality of the post-doc experience, mentors should expand the opportunities that are provided. Specifically, by viewing their postdocs as future colleagues, they will advocate for their advancement, engage them in regular teaching activities and provide opportunities for increased responsibilities and leadership. Lastly, postdoc specific programs should include opportunities for postdocs to interact scientifically and socially with other postdocs in varied research areas that may range from fundamental discovery science to clinical research. For example, K awardees (career development awards) have a multitude of opportunities for scientific interactions and broad-reaching academic experiences; postdocs should be included in these activities as well.

Existing NIH policies, programs, or resources

Financial challenges: One existing program that the NIH has is the NRSA childcare support program (i.e., $2,500 yearly). This program could be expanded to cover additional childcare costs (>$2,500 yearly) and additional life expenses (e.g., moving expenses, commuter support for transportation/parking; at our institution in the Bay Area, parking is not guaranteed and is incredibly expensive). In addition, funding programs for K awardees include supplemental support in the case of critical life events (i.e., Administrative Supplements to Promote Research Continuity and Retention of NIH Mentored Career Development (K) Award Recipients and Scholars). Similar supplemental opportunities may be considered for postdocs.

Proven or promising external resources or approaches

NIH engagement of national (i.e., National Postdoc Association) and representative state postdoc associations can help inform the existing need and ecosystems across the country. A proven external approach that the NIH could adopt to enhance the postdoctoral training ecosystem relates to opportunities for international postdocs. Many foundational postdoctoral awards allow international scholars to be eligible for their awards. In our department, many highly qualified postdocs come to our programs from international settings. However, since they are not US citizens or permanent residents, they do not qualify for NIH postdoc support. A more inclusive policy should be considered by the NIH.

Response 1939

Perspectives on the postdoc roles and responsibilities

Traditionally, postdoc training has been seen as a pathway to an academic research career. But those opportunities are fairly few and the probability of success is low.

When we ask our best and brightest young PhD scientists effectively to put their lives on hold for 3 years (or more), they ought to know why and what realistically the outcome is likely to be; many hope for an academic faculty career, and many of those will be disappointed.

I contrast the career progression of the science postdoc with professional training for medicine, law, or even business or technology.

It's not all bad: the upside for postdocs is that, if they are successful, their work and lives will most of the time be meaningful, honest, and interesting; there aren't many careers where that can be said.

Fundamental issues and challenges

It's very clear that we need to increase the stipend substantially to increase recruitment, retention, and quality of life. We are asking our best scientists effectively to put their lives on hold for several years while training for a job that may never materialize.

When postdocs see few real academic jobs, and industry will pay them a lot more, retaining them in the academic research pool is difficult.

Existing NIH policies, programs, or resources

Policies and procedures that make it difficult to supplement postdoc salaries from other grants exacerbates the problem of low stipends.

Proven or promising external resources or approaches

Can we look at models in Europe? I'm not sure that the situation is any better, but my sense is that several European countries -—France (INSERM), Germany (Max Panck Institutes) for example -—have established public scientific research career models that don't require quite such a relentless individual competition for funds to conduct research and, incidentally, to provide food and shelter for one's family. I guess internal research careers at NIH might provide this security, but in academic research, if you don't have a tenure track faculty position, a biomedical research career is too precarious an option for many people to pursue.

Response 1940

Perspectives on the postdoc roles and responsibilities

Help in whatever ways needed for PI/professor to advance projects, secure grants, communicate research at meetings/symposiums, publish papers.

Provide input and argument that will guide direction of PI's research programs.

Complete experiments efficiently and with high quality within few iterative attempts.

Take care of the lab space and equipment, supervise graduate and undergraduate students as needed.

Organize and spearhead new research endeavors, leading others as needed, quickly assessing feasability.

Help foster and strengthen collaborations that will help your PI's lab, and build your own network.

Help recruit and interview new lab members.

Learn all that you can about running independent research program and lab management from all of the above points. This includes the inner workings of all steps of getting funding, publishing, dealing with politics.

Follow own ideas, read about areas of personal interest, and propose new projects, or, build idea portfolio for own future career.

Read the literature and talk about it with peers and faculty.

Fundamental issues and challenges

Postdocs are supposed to be temporary, training for advancement to a position in the future with greater independence and responsibility. Therefore, there is discomfort in confronting questions such as "how long will I be here," or, "how much of a contribution will be enough to graduate from this postdoc." Because there is no graduation date, you run the risk to becoming medium-term cheap labor for a PI for several years as an end in itself.

A postdoc is obviously helpful in building your career towards getting a tenure track faculty position. However, the ferocious competition for and statistical unlikelihood of landing one of those jobs makes the prospect of taking a postdoc position in pursuit of a tenured position seem like a waste of time. Additionally, It is not perceived as being helpful in getting an industry job, and as stated by some recruiters I've spoken with, it can count against you in many resume pools.

And money, probably. It is not a good feeling being in your 30's and earning less than someone in their early 20s who has less experience and education and works a less technically and temporally demanding job. Personally though, I am not bothered when looking at it from the view that the low pay is probably related to the nature of the sources of funds and also the low level of economic risk personally taken on by postdocs, and the low probability that your work will yield a high economic return in the short term.

Existing NIH policies, programs, or resources

A major goal of NIH-sponsored postdoc work should be to develop a given postdoc into a productive, independent scientist within a resonable timeframe (2-3 years). NIH policy and fundamental aims should reflect that to help shove postdocs out of the nest of dependence of their PI and more towards writing their own grants and pursuing and defending their own original ideas. Even if scaled down and broken up into smaller exercises of gradually-increasing risk. So, maybe a new model could be shorter appointment periods or limits, higher pay, but higher expectations and greater demand for demonstration of growth towards independence.

Limit politics.

Proven or promising external resources or approaches

Find and talk to the people who left academia after working as a postdoc.

Response 1941

Perspectives on the postdoc roles and responsibilities

I view the postdoc as a necessary step to advance in an academic career, as well as some non-academic research careers. I feel that the learning that can occur in a postdoc is very valuable. However, the job is incredibly underpaid and my institution ([redacted for anonymity]) hires us (as T32 fellows) as 1099 contractors and requires that we pay tax on our own benefits, which leads to me being paid $61,500 and having an 30% tax rate—outrageous and untenable.

Fundamental issues and challenges

The **Fundamental issues and challenges**—at least at my institution—are

a) our status as 1099 contractors and being taxed on imputed income,

b) delays in pay up to 4-6mos on average—I know at least 10 fellows who have experienced this—at the start and/or renewal of our 12-mo contracts.

We have no choice but to work during these months w/o pay because if we delay our work we are only hurting ourselves. Postdocs are severely underpaid across institutions, have long hours, and oftentimes deal with toxic, abusive mentors who are unchecked and not held accountable. I have experienced this firsthand and witnessed this among countless fellows at my institution and have heard from countless other postdocs at other institutions.

Existing NIH policies, programs, or resources

NIH should

a) Increase pay for postdocs on NIH-funded grants (like the T32)—$70K in NYC would help a lot,

b) Require institutions hire postdocs as W-2 employees, not 1099,

c) Ensure we are not taxed on our health benefits, and really one of the most important things is—

d) Require that mentors have to be evaluated before they are allowed to receive grants and hire postdocs. There is rampant toxicity, harassment and abuse among postdoc mentors. These mentors take advantage of postdocs and severely impede their ability to advance in their careers. I have seen this across institutions—it is systemic and there are no evaluation systems, and no consequences for faculty's behavior—esp if they are tenured—leadership just pushes these things under the rug. I have opted out of a career in academic medicine given the toxicity.

Proven or promising external resources or approaches

NIH could provide external mentors for postdocs outside of the institution—I had a difficult time finding mentorship as everyone at my institution is very competitive, not collaborative, and took things personally if I asked for help from someone else. People were also untrustworthy. At the same time, I think given the fact that we're called "trainees" postdocs are also babied—there's all this talk about mentorship but we're not given proper mentorship (faculty have no time because they constantly have to write grants), and at the same time, we're not given the freedom to exert our own independence and develop our ideas. There were multiple times throughout my postdoc where I had ideas for projects that I think could have

facilitated my independence but the institution and my funding mechanism dictated that I needed a mentor—and I think this impeded my ability to progress in my career. More smaller grant opportunities for postdocs without the need to be mentored by faculty mentor (consultants would be fine) would help this.

Response 1942

Perspectives on the postdoc roles and responsibilities

It's a medium stage between graduate student and IP. You have developed the technical habilities to perform experiments, now you need to learn how to manage a team, develop projects, apply for funding a at the same time that you perform experiments to continue getting publications

Fundamental issues and challenges

Salary is very low compared with the industry or other similar jobs t. The NIH postdoc salary recomendation barely covers the cost of life in some states.

Difficulties to balance personal life and work

Diffiulties to continue the path in the academia. Lack of grants for non-US citizens

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

More mentory grants

More facilities for parenthood.

Salary

Response 1943

Perspectives on the postdoc roles and responsibilities

Not all academic postdocs have the end goal of becoming an independent PI, for me this is the main purpose but for those people my thoughts do not apply.

But this is tricky. People may think, postdoc is to put the cherry top of your training and boom you're ready to be a PI. Hence the creation of the baffling early K99 (>2 years of postdoc). Sadly good people find themselves in bad grad school labs and their training is lackluster. Meaning the training required at postdoc is much more substantial.

My view on a postdocs responsibilities are, that it is all your responsibility as a postdoc. It's YOUR project, YOUR career, YOUR independence.

Because of that being a postdoc is about so much more than just data generation. That is a technicians job and I wish PIs had a better appreciation of that.

Postdocs need to:

Generate data

Develop ideas

Network

Mentor and Lead

Write papers

Write grants

Stay on top of the literature

You cannot do all of these things at the bench 65 hours a week. Usually, mentoring and leadership suffers. Hence we have a population of PIs that don't know how to manage people or train people or lead a team and the people in those labs usually suffer. Also, time to stop and think about what you are actually doing

is also a good thing. I have seen people running around like headless chickens doing experiments that don't answer the question because they're so focused on having to be busy and producing something. Anything! Apparently, even if it is junk.

Fundamental issues and challenges

I watch a Youtube show about personal finances, it's fun and the guy yells at people for taking on silly credit card debt. But what shocks me is that 24 year olds with a bachelors and no experience are earning as much as me, a 6.5year academic postdoc. No matter how you shake it, we are vastly underpaid for the amount of training we have. People like to remind us that we are trainees and that is why we earn a trainee salary. I frankly think the language and ideology there is insulting. Of course we are trainees, and we are training to be world experts so it takes more time than other industries but it doesn't mean the money is right.

Money isn't everything, but there ultimately comes a time where you ask yourself is the juice worth the squeeze? Most postdocs ask themselves this three times a week. It's tough, we work our butts off, for poor pay and sometimes for PIs who take advantage. Submit our ideas as their grants. Don't support us in our path to independence and just use us as cheap(ish) labor. No wonder people don't stay.

I will say I love my job. But it's effing hard. There are good days and bad days. My wife and I are both postdocs, working hard, generating data, submitting grants. But we have had discussions about starting a family and don't see how we can right now. This is something that needs to be addressed. Silly time constraints on K99s and closing of viable pathways to independence based on time do not help.

All I want is a FAIR chance, give me that, get the hell out of my way and I can do this. I can become a brilliant independent scientist. But I need the chance.

Existing NIH policies, programs, or resources

This situation may be unique to my institute but my suspicion is that it isn't. 65-70% of our postdocs are international and are on visas. This makes a large proportion of the academic postdoc population unable to apply for the majority of NIH fellowships. As I mentioned in the barrier to success section, the lack of a viable path to success is a limiting factor in postdoc retention. But you are losing a large swathe of international postdocs, who either return home or simply feel like the NIH do not support them and say to hell with academia, if and when I get my green card I'll switch to industry.

Another area of concern is the time limits placed on K99 applications. Everyone is on a different timeline and pathway to independence. For me I changed field completely, so I had to almost retrain for the first 2 years of my postdoc. I'm lucky my PI was very supportive and patient, but I'm now ready to push for independence but I'm in my 6th (nearly 7th) year so the K99 route is no longer accessible, so instead I submitted an R01, which will obviously come with it's own challenges. Again, this all points back to a lack of a viable path to success.

Proven or promising external resources or approaches

Open paths to success.

This isn't strictly true, but is for the majority of top institutions;

To get an independent position, you need an R01.

To get an R01 you need an independent position, because track record. independence from mentor. etc

It feels like a closed shop.

Extend to K99 to 8 years, give people a chance to grow and develop at their time. Not some arbitrary number someone who went through this a generation ago thinks is an acceptable time. Training takes longer now, long gone are the days of a Nature figure being a couple of western blots. the K99 should reflect that.

Response 1944

Perspectives on the postdoc roles and responsibilities

I see a postdoc as a stepping stone to a faculty position. A time to gain additional mentored experience, build my network and develop the expertise in my program of research to be competitive for future positions. This should be time-limited, 2-3 years at the most.

Fundamental issues and challenges

- Low professional status (e.g., do not receive benefits of faculty, cannot apply for many grants as PI, cannot independently support research assistants or students)
- Unclear path to promotion, so much uncertainty in career trajectory. Difficult to manage with a family, and young children.
- Low pay for years of experience and academic attainment.
- Only 6 weeks of paid parental leave.
- Very competitive and stressful path to career stability (e.g., NIH K awards, pulling together multiple sources of funding)

Existing NIH policies, programs, or resources

- More $ for K awards
- More frequent submission deadlines for K awards (this would allow shorter turnaround for revisions)
- More structured post-doc to faculty pipelines

Proven or promising external resources or approaches

No response

Response 1945

Perspectives on the postdoc roles and responsibilities

Study and analyse research papers, perform independent research leading towards publication(s) at the end of every year.

Fundamental issues and challenges

Lack of proper interaction on research, counter-productive research groups, i.e., no scope to publish or perform computations.

Existing NIH policies, programs, or resources

Regular supervision of personal investigators, who have hired postdocs. Get research plan sent to NIH, evaluate both faculty mentor and postdoc every 6 months if things are according to plan. Check if faculty mentor is emotionally stable human being and is a situation to guide students.

Proven or promising external resources or approaches

Create metrics for academic faculty based on data obtained from past and present PhD and postdoc researchers.

Response 1946

Perspectives on the postdoc roles and responsibilities

PostDoc positions are often viewed as trainee positions. I disagree with that view and think it is used to apply exploitative labour practices. PostDocs are the worker backbone of the academic research enterprise. They perform experiments, train junior trainees, and in bigger effectively run research operations, because principal investigators often end up being too busy. PostDocs start their positions having completed extensive training, having received the most advanced degree that academic institutions can issue, a PhD, so to characterize them as trainees is absurd. I see PostDocs as qualified workers that deserve more respect. It serves as position to gain more independent experience in order to qualify

oneself for a future principal investigator position. However, gaining experience and getting trained in additional skills / techniques is the reality for non-trainee, stable jobs in other industries as well, so these aspects simply cannot serve as an excuse to classify PostDocs as trainees in order to underpay them.

Fundamental issues and challenges

The answer is simple: The pay is criminally low given the level of qualification **and responsibilities** that PostDocs have. Benefits are often minimal and saving for retirement usually is impossible. PostDocs tend to be at a stage in their lives where they'd like to start a family and most can simply not financially afford to do so, which is an absolute shameful reality. Any job, but particularly one of such importance for our society that involves such extensive training and advanced skills, NEEDS to pay enough for the worker to live a comfortable life and start a family. PhD graduates now find more and MUCH better paying alternatives than ever in the industry / biotech sector, where they feel less stressed about their future and more appreciated for their skills, so academic positions are simply too unattractive for most people after finishing graduate school. This is no rocket science, these issues have been ongoing for decades, and workers are finally expressing their dissatisfaction with consequences for those that have the power to change the status quo. Pay us more money! We deserve it.

Existing NIH policies, programs, or resources

NIH grants issued to principal investigators DESPERATELY need to increase! In order for PostDocs to be paid more, PIs need to be able to spend more. Universities need to reduce spending on administrative workers, which as blown up in recent years, and instead commit some of their enormous wealth to supporting workers supporting their core missions—educations and research.

Proven or promising external resources or approaches

Recent efforts by PostDocs to unionize in various academic institutions across the US (e.g. UC, Mount Sinai, Columbia U, University of Washington) can inform you about what PostDocs want: Higher pay, better benefits, safer working conditions and a desire to actually be seen and listened to.

Response 1947

Perspectives on the postdoc roles and responsibilities

For those interested in academia, a postdoc should help an investigator begin to develop their own line of work. This includes training in grant writing, new methodology, and publishing work in their field, but should focus on making someone independent by the end.

Fundamental issues and challenges

Money, inclusion in the workplace, and opportunities for independent funding.

Graduate stipends are already very low, and after spending ~5-6 years working towards a PhD, many cannot afford to do a postdoc. We need to raise stipends, especially if we want to recruit and retain those who may have families, want to raise children, or be taking care of other family members (work that predominately falls on women and those historically excluded from science). Additionally, we need to improve diversity, equity, and inclusion in all academic spaces, because all too often we are pushing out those historically excluded from science before they can really even consider if a postdoc is something they'd like to do. After suffering from systemic biases and microaggressions throughout graduate school, many people don't want to deal with it again for 3-6 more years, especially if they're not getting adequate pay. Funding agencies and universities must prioritize training and supporting those who are working to make science more inclusive for all. Finally, there need to be more sources of funding for postdoc projects. Relying on our PI's existing funding limits the experiments we can do that don't fall within their grants, forcing us to stay much longer completing their projects and working on our own preliminary data.

Existing NIH policies, programs, or resources

We should greatly expand the K programs to fund more young scientists and fund more of their own experiments. Additionally, we should require regular participation in DEI trainings for all NIH funded investigators.

Proven or promising external resources or approaches

No response

Response 1948

Perspectives on the postdoc roles and responsibilities

In my eyes the postdoc position is a critical part of the research process and we often serve as the "in the field" leaders of our groups and teams. We are often conducting research at the forefront of each field and will have both primary and supportive roles in most of the research being conducted in our area of expertise. This means we have the unique role of being simultaneously learning how to be better researchers and manage people, while also helping others learn their essential research skills.

Fundamental issues and challenges

I think the biggest issue is the underappreciation of the role. It is historically underpaid, particularly considering the amount of stress and quality of life aspects of the job. Since graduate school often requires pausing one's life, we postdocs are hoping to restart our lives and jump-start our careers, both of these goals are greatly hampered by the current system. At the current time, we are grossly underpaid, and therefore many cannot pursue postdocs (and therefore cannot pursue academia) as it would simply leave them too financially burdened.

Postdoc mental health is also worse than ever. In graduate school, one is just as likely to graduate as one is to develop a mental health disorder (such as anxiety, or depression), and when we become postdocs these mental health aspects do not just go away, but the support networks built by universities do go away, which can leave us marooned in a new high-stress job, in a new city, financially stressed. A perfect storm for mental health.

Additionally, the point of a postdoc is becoming increasingly opaque. The near stagnation of faculty positions, and hiring freezes in the cooperate sector are not compatible with the high turnover nature of a postdoc. It is becoming increasingly common for postdocs that would have only needed a year or two a decade ago to need 4 to 5 years, and for each postdoc year the opportunity cost only increases.

Existing NIH policies, programs, or resources

I think pay is the lowest-hanging fruit, followed by more universal standards for benefits and support. If we want postdoc positions to be competitive again we need them to be more desirable positions, with clear paths to success and other benefits. I do not think one or two changes can necessarily do that, but we need to stop thinking about postdocs as expendable researchers, and more as future faculty or future industry leaders.

Proven or promising external resources or approaches

Honestly look to countries without this problem, like the Europeans.

Response 1949

Perspectives on the postdoc roles and responsibilities

Bridge between faculty or industry position and gradaute training. An opportunity to acquire new skills, train for the next stage in career.

Fundamental issues and challenges

Inhibition of recruitment, retention and overall quality of life is directly related to payscale. increase pay and you will have more postdocs doing academic research. You can solve a lot of issues by throwing money at it.

Existing NIH policies, programs, or resources

1. NIH policies should consider increasing Fellowship and Training Stipend Levels taking into account the regions that most postdocs are concentrated in (west coast east coast and chicago) are very expensive to live in. Inflation should also be taken into account. The increase in pay in from one year to the next is barely $160/month.
2. NIH parental leave policy is outdated. 8 weeks of leave for a fellow on a F32 is unacceptable. It should at least be changed to 12 weeks paid leave.
3. NIH funding for F32—postdocs should also include health insurance coverage for the fellow as well as the dependents. By allowing institutions to do as they wish results in abuse of power where institutions refuse to pay dependent health insurance and make fellow pay out of pocket.

Proven or promising external resources or approaches

No response

Response 1950

Perspectives on the postdoc roles and responsibilities

Training position

Fundamental issues and challenges

Universities are having mandated increases in postdoctoral salaries, but NIH (nor the university) is not covering these increases through supplements to grants. Because of this, grant holders can't afford to hire additional personnel and/or perform experiments due to having to re-budget to cover the cost of these increases. This leads to postdoc dissatisfaction and potentially having to make the postdoc redundant due to an inability to cover salaries and benefits. In some instances, such increases may make paying for a postdoc cost-prohibitive, which then defeats the purpose of the entire system.

Existing NIH policies, programs, or resources

Additional career development awards

Proven or promising external resources or approaches

No response

Response 1951

Perspectives on the postdoc roles and responsibilities

I think a postdoc should be growth in skills required for a faculty position—ie grant writing, management of a lab, growth of scientific skills. It is a mechanism to improve your ability to get a faculty position. As it stands it labels who have a PhD as trainees which is in my view belittling and inaccurate. All desirable jobs involve training and have opportunities for advancement there is no reason to label postdocs as trainees except as a mechanism to justify the embarrassing wages which they are paid.

Fundamental issues and challenges

Postdocs are not paid enough. I can get a job in industry paying 5-10x more than a postdoc after my PhD. After spending 5+ years not contributing to my retirement it would be financially irresponsible for me to take a postdoctoral position. That is why I wont be applying to them and a serious issue with recruitment. To improve retention and quality of life obviously paying people closer to their value, but treating postdocs as closer to independent researchers and having them in environments where their goals align with that of whomsoever lab they are in also would help.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1952

Perspectives on the postdoc roles and responsibilities

To me it is a crucial experience where you can gather research experience, techniques and general management skills before pursuing a faculty position.

Fundamental issues and challenges

The only issue is salary. The compensation for the role is far too low. Most US citizens go to industry where they will be compensated fairly whereas the majority of postdoctoral trainees are becoming international. When I speak to others the international trainees often use the position to get a US residency card to move into industry. It is very difficult for an individual to survive alone on a postdoc salary let alone have a family or live comfortably.

Existing NIH policies, programs, or resources

Forced minimum salaries. The guidelines are often not met, particularly in high living cost areas as well as yearly increases do not exist.

Proven or promising external resources or approaches

Increase salary will improve every aspect of the position.

Response 1953

Perspectives on the postdoc roles and responsibilities

Postdocs are in a transitional stage. Many, particularly those that want academic postings, are aiming to be faculty. But they are really looking for experience beyond their PhD to figure out what their next steps are.

Fundamental issues and challenges

The job sort of sucks. I was a domestic PhD student looking at my postdoctoral options, and any kind of NIH-funded position was unappealing due to low pay. I ended up in a national laboratory, where my starting pay for a named postdoc was $89k. Now that I'm on the other side of the hiring equation, you see immediately that many of the candidates willing to work for the low pay that comes with an academic postdoc are from abroad, who are primarily driven by even lower pay back home. The job just isn't competitive when the hours are long, the pay isn't commensurate with educational attainment, and so potential postdocs that have alternative job opportunities take them in droves.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1954

Perspectives on the postdoc roles and responsibilities

Postdoc is an opportunity to fully develop one's independent scientific career under the mentorship and support of a funded researcher or organization.

Fundamental issues and challenges

There is a highly variable quality in postdocs that I interview. I have a perception that well-qualified postdocs tend to go to larger and more recognized labs. Retention in my lab has been reasonable. Covid aside, my perception is that trainees have a good quality of life as I don't demand specific hours or tasks of them. I don't believe my approach is particularly common though.

Existing NIH policies, programs, or resources

I think a big topic that NIH will have to grapple is what to do about equitable pay for postdocs. PDs are paid quite low relative to industry (my salary went down by almost 2/3 when I left industry for a postdoc), so there is little financial incentive for potential recruits. On the flip side, paying them competitive wages (which would likely exceed mine as a faculty member!) would very easily consume the majority of an R01.

Proven or promising external resources or approaches

I'm not sure what NIH is doing in terms of postdoctoral recruitment, but their efforts on the other topics (training, mentoring, work environment) are apparent.

Response 1955

Perspectives on the postdoc roles and responsibilities

With funding uncertainty I feel uncomfortable committing to hiring a postdoc who may expect to stay longer than the typical 5 years of an NIH grant.

Fundamental issues and challenges

Students see the issues faced by academic faculty and decide that industry is a more secure and better paid option. I also think that industry offers clearer guidelines on job expectations and more consideration to quality of life. I also hear that postdoctoral recruitment is hard at the moment, which discourages me from looking to hire.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1956

Perspectives on the postdoc roles and responsibilities

I am currently wrapping-up my PhD. My plan was to finish my PhD and find a job in industry. However the more I look the least qualify I feel for positions. I am considering a Postdoc as a way to generate new skills and become more marketable in industry. However the post-dock pay wage make this a hard commitment to make.

Fundamental issues and challenges

Pay wages. Most post docs pay between $70-80K/yr. This isn't competitive in CA. Industry jobs usually start around $100-110K/yr.

Existing NIH policies, programs, or resources

Create postdocs positions that would guarantee preparation for industry jobs. I find it scary to commit multiple years to not generate transferable, highly sought after skills.

Proven or promising external resources or approaches

No response

Response 1957

Perspectives on the postdoc roles and responsibilities

It should be a gate for exploring several aspects of being a successful researcher/PI. This may include teaching as well.

It should not only be viewed for the completion of PI's work but also needs to focus on how a PI more importantly successful PI's are groomed.

Fundamental issues and challenges

In an academic setting and based on personal experience, the benefit is pretty low compared to industrial ones. With a few exceptions, academic PI's are focused only on the completion of their grant work, rather than including them in professional development like involvement in grant writing/renewal, and helping in individual grant preparation.

Most international scholars, view it as a step toward getting their permanent residency before joining to industry. And the PI's exploit on this basis.

Existing NIH policies, programs, or resources

Please extend NIH policies to all the institutions too, to create an environment where postdoctoral training is also a respectable position.

Proven or promising external resources or approaches

Response 1959

Perspectives on the postdoc roles and responsibilities

Ensure career development as whole. This comprises of creating your own niche in terms of research expertise along with providing proof that you can accomplish it by publishing meaningful science.

Fundamental issues and challenges

Payscale—The scale up from PhD to a postdoc position is not sufficient.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1960

Perspectives on the postdoc roles and responsibilities

A post doc is intended to be knowledgeable in all basic lab skills, and several advanced skills and material from previous lab. In post doc they should learn new techniques and expand knowledge into new area as well as have opportunities like networking and learning with a career related focus.

Fundamental issues and challenges

Post docs are at an age where they are buying houses and having children, so living off a low income as a post doc is not sustainable and many graduates may skip it due to salary. It is also hard to drag a spouse and family to a new location knowing that it is a temporary job.

Existing NIH policies, programs, or resources

Higher salaries are good but also funding poorer labs in more spread out areas allows for post docs to work more locally without uprooting their family will result in more overall post docs, or at least add a moving allowance to make it easier

Proven or promising external resources or approaches

The universities treat us as though we're disposable intern workers. We get worse health insurance than the faculty and students and receive less than $500 a year from the school to fund post doc events. No community amongst us. Higher salary and better treatment from universities will help

Response 1961

Perspectives on the postdoc roles and responsibilities

A postdoc position is in weird transitional space, where the postdoc is both an employee and an individual seeking out further training. I propose that a postdoctoral experience should be a protected time to allow for an individual to expand beyond their graduate training, gain experience with grant writing or teaching depending on career path, and conduct their own research. Although postdocs will be attached to labs; these attachments should fundamentally be symbiotic with both the lab and postdoc growing from the attachment. Additionally, all postdocs should have the financial stability required to engage in deep thinking and research without the burden of service or teaching. Postdocs need to be treated as junior faculty, engaging in the research activities required to establish their independent lines of research and national reputations.

Fundamental issues and challenges

There are two common and contradictory assumptions about postdocs that are hindering and damaging to academic postdocs:

a) a postdoc is a lab manager who does not need career development or their own research time and

b) a postdoc is "glorified doctoral student" who is too junior to assume responsibilities over their own time and research. If a postdoc is nothing more than a lab manager, then they should be paid and treated accordingly, i.e., competitive salary, retirement benefits, etc. If a postdoc is a "glorified doctoral student," then they should receive more protections, access to appropriate developmental resources, and their postdoctoral time should not count against their early stage investigator time.

These two assumptions highlight the fundamental issues for recruitment, retention, and quality of life. Both assumptions pay postdoctoral scholars too little, provide them little to no protections from abuse, bullying, or retaliation, undermine their ability to save for retirement, and instill barriers to adequate health care. These problems are exacerbated for women, trans-individuals, individuals with disabilities, people of color, parents, and visa-holders.

By placing postdocs, writ large, under the power of one PI who then decides what type of postdoctoral experience they want, we create the space for abuse of power.

Existing NIH policies, programs, or resources

Fundamentally, there is a culture change that needs to happen. This cultural change needs to affect the structural supports for postdocs, moving them away from being "someone's postdoc" and into a space of engaging in a "postdoctoral experience." Below are some actions that NIH could explore that are already in place.

1. Increase childcare support for postdocs with children
2. Require all PI and postdoctoral mentors to participate in training around the ethical treatment of people, such as Raising Resilient Scientists, and require continued refresher courses
3. Increase allowable vacation days to 35 (minimum; current max is 15)
4. Expand existing methods of reporting abuse and bullying, such that postdocs can report abuse and bullying to an outside party and then follow through on investigations by taking actions against the PI while ensuring the postdoc's privacy is maintained
5. Increase salary caps or provide alternative methods for increased compensation

Proven or promising external resources or approaches

Here are some additional approaches that should be explored,

1. Explore the possibility for visas to be held at the university level by a neutral party—not the PI
2. Allow postdocs to save for retirement without being penalized

Response 1962

Perspectives on the postdoc roles and responsibilities

Academic Postdocs are the most underpaid entity in the whole Accademia system. They are expected to work hard all the time sacrificing their own personal life. Even though they work so hard, there are still chances that they can get fired from their job any time. In short, there is no job security. So, in my view, the postdoc position is nothing more than a trainee position where expectations are high, stakes are high but its only one way. There is no way that the Postdocs are getting benefits also. Only the PI creates endless pressure to have their own benefits.

Fundamental issues and challenges

Visa issues, Lab environment, over expectations are the basic challenges a Postdoc experiences.

Existing NIH policies, programs, or resources

Salary should be increased definitely.

The advisor or PI should also get training about mentorship. They should learn how to train a postdoc.

This kind of review process (RFI) should be done frequently where the Postdocs can share their thoughts.

Proven or promising external resources or approaches

No response

Response 1963

Perspectives on the postdoc roles and responsibilities

I view a postdoctoral position as a career path only seriously considered by someone who aspires to become faculty at an academic institution. It is an opportunity for a recent graduate to work under an established principal investigator at a respected university to learn how to run an academic research lab. The position has a lot more responsibilities than that of a graduate student because there is an expectation of scientific competency that was acquired during their graduate work.

Fundamental issues and challenges

Money. Postdoctoral positions in the United States are grossly underpaid for the skill required to obtain the job. Considering that the average salary for a postdoctoral position in the United States starts at ~$49k and industry positions can pay anywhere from double to triple that depending on the research area. Working as a postdoc in an academic lab often requires more the 40 hours a week for less money than you can make elsewhere. There is also no guaranteed of a faculty job upon completion a postdoctoral position either. Ultimately, qualified graduate students choose to not pursue postdoctoral positions because its extra years of their lives where they are unable to recoup the investment that they have made into their training and education.

Existing NIH policies, programs, or resources

I am not familiar with existing NIH policies, programs, or resourcesbecause I have not seriously considered pursuing a postdoctoral position for the reasons I have outlined in the fundamental issues.

Proven or promising external resources or approaches

Other than increasing the salary to be competitive with industrial positions there is no proven way for the NIH to be competitive for recruiting qualified scientist to work in postdoctoral position.

Response 1964

Perspectives on the postdoc roles and responsibilities

Primarily to participate in state of the art research

Fundamental issues and challenges

Resources of all kinds

Existing NIH policies, programs, or resources

Nor sure

Proven or promising external resources or approaches

Not sure

Response 1965

Perspectives on the postdoc roles and responsibilities

The postdoctoral training period is a special time to be a scientist. For those with ambitions in academia, it is the last time you will be in a fully mentored position and the last time that your main professional responsibility is research. That said, I think that postdoctoral training programs (and individual mentors) could do a much better job of training postdocs for all of the things an academic career will entail beyond the bench. To be competitive for independent academic careers, postdocs are told that they should be "well-rounded", which in my experience roughly translates to being connected and active in their broader scientific communities, developing effective mentoring and communication skills, and participating in initiatives to support graduate and postdoctoral training at their home institutions. However, as a postdoc, most funding sources only support research activities, meaning that there is an inherent bias such that only those who have access to support or resources outside of the meager postdoc salary will be able to participate in such "extracurricular" endeavors.

Fundamental issues and challenges

Postdocs are not paid a living wage. Most postdocs have to choose between their research and their personal lives, or are forced to leave academic research positions if they are not able to support their needs. The idea of a 2-3 year postdoc is antiquated.in the biological sciences, most "successful" postdocs remain postdocs for periods of time that are often longer than their time as PhD candidates. Recent doctoral graduates are not blind to this and are fully justified in seeking alternatives to postdoctoral positions.

Existing NIH policies, programs, or resources

EXPAND THE ESI ELIGIBILITY CRITERIA. Why should someone's time as a postdoctoral trainee count against them as they transition to an independent position in academia? The ESI period should start on the start date of one's independent academic position. The current system favors those who got "lucky" in their postdocs and were able to move on quickly to start their independent careers, but not all biomedical research moves quickly.

Proven or promising external resources or approaches

No response

Response 1966

Perspectives on the postdoc roles and responsibilities

I feel that postdocs really carry many research directions forward. I view this training opportunity very favorably because of my particular experience at my institution and under my PI. I know many are not as fortunate and I think that more equitable practices would be better for others. I'm not sure the best way to hold PIs accountable so that they behave with integrity. (I have heard horror stories or even seen friends, typically non-citizens, who are threatened with losing their role/position and thus visa status directly by their PI).

Fundamental issues and challenges

A major challenge for recruitment of postdoctoral fellows is that the high value placed on different training experiences often requires postdoctoral fellows to relocate to a new institution (many times in a different state). Yet very few, if any, universities provide relocation expenses to postdoctoral trainees. This means that a trainee coming from a PhD with a stipend that barely meets a living wage now has a multi-thousand dollar relocation expense in order to accept a competitive postdoc. This selectively disadvantages trainees with fewer resources at their disposal (either from family, spouse, etc.) or those who cannot relocate for personal reasons.

Existing NIH policies, programs, or resources

When I began my postdoc, I was supported on a IRACDA K12 training grant, which included benefits (insurance, retirement, employer match, etc.). My career goal is to become an independent investigator, which requires a track record of securing independent funding. This means applying to fellowships (e.g. NRSA/F32, foundation fellowships, etc.). Unfortunately, when I received my NRSA, I lost those benefits, which is inexcusable. Luckily, my department was able to support my health insurance, but I still lost retirement benefits/options. Many are unable to save for retirement during their PhD, leaving most postdocs in a situation where they have lost ~8-12 years of potential retirement savings, early in the career when these savings have the biggest impact! I understand that most fellowships do not include overhead that would cover these benefits, but the NIH should be able to require these institutions with multi-billion dollar endowments to adequately support their most vulnerable trainees, who are carrying out the research projects that bring in grant money.

Proven or promising external resources or approaches

I had an amazing experience as an IRACDA K12 postdoctoral fellow. I am a huge proponent of cohort based trainings and think that more cohort-based initiatives would enhance the postdoctoral training ecosystem. There are many training grants, etc that attempt this, but I think the value of the IRACDA program is that it brings together postdoctoral trainees from different cultural/societal background AND from different scientific backgrounds.

Response 1967

Perspectives on the postdoc roles and responsibilities

I view it as a temporary position (2-5 yrs) meant to train early stage scientists that want to gain expertise in a new area. They should be getting up to speed quickly and driving productivity that will positively impact their career trajectory. This is a make-or-break time in their career development.

Fundamental issues and challenges

Salary and mentoring. The salaries are not as competitive I would guess and with the re-assessments that are taking place throughout the workforce, they are looking for greener pastures that pay well. Academia cannot compete. As a PI, I can’t spend more on a post-doc salary with the restrictions on budgets for research grants. They have not grown so I cannot compete with a company. Post-doc salaries have increased through NIH standards, but it is probably still not competitive.

I think retention is also negatively impacted by the lack of formal mentoring. Postdocs are not getting the same attention as other trainees at different levels, and so it becomes highly variable from lab to lab. And some PIs view these trainees as data generators. They are not getting good training and there is often no formal committee to advise them or help them with their career development. It currently falls to the PI.

Existing NIH policies, programs, or resources

Implement similar standards for institutions to support post-doc mentoring and training. Training grants for post-docs can be encouraged to implement these better policies throughout institutions.

I am not sure how you change salary tbh. Without more funding, there may be less money to go around. Is the compression in post-doc number reflecting the lack of growth in NIH funding. We are supporting more labs, but is this a necessary compression on a system that has become too bloated?

Proven or promising external resources or approaches

Having institutions establish formal mentoring committees would be a great start. Resources that support post-doc mentoring would be great to make this more common throughout academia.

Whaat are industry partners doing? Is there a way to partner to create career development options?

Response 1968

Perspectives on the postdoc roles and responsibilities

Postdoctoral position (from my point of view) is an entry position to academic faculty jobs, since post docs are not mandatory for academia. In post doc the person is supposed to start developing semi-independent research in the lab the are affiliated to & with the mentor of the lab.

Fundamental issues and challenges

the most prominent problem by far is the pay gap between post docs position and industry jobs, there is even a huge pay gap between post doc positions in the industry and that in the academia. the low pay (not sure if we can call it a salary, it looks more like a glorified graduate student stipend) makes post doc jobs in the bottom of the job selection.

the second limitation is mentoring; while post doc is looked at as a "training", most PIs I know deal with post docs as a fully fledged person who does not need support (but they don't pay them as full time job). and in many cases I the PI brings a post doc to do something the PI don't know anything about.

third limitation would be the immigration issues facing international post docs due to many things. The narrow window allowed to move between positions without having to exit the US and re-enter with new visa makes it harder for international post docs to move easily between labs.

last but not least, I would like to shed light on how toxic the academic environment became. Every PhD graduate have experienced/ seen a fellow graduate student experiencing some level of toxic behavior by their PIs, and a lot of PhD graduates don't want to stay in academia for this exact reason. After what students experience in graduate training, the vast majority don't want to work in a training job nicknamed "grad school 2.0".

Existing NIH policies, programs, or resources

As an international post docs, I find it hard to find a postdoctoral fellowship here. the available training funds is very limited and that makes it overly competitive (imagine that ALL international graduates are competing on the SAME fellowship).

Salary policies need to be modified to better pay. If you think about it, it is unfair that a person with the "highest" attainable education level (PhD) is paid a salary below or at best cases equal to the "average" salary for their age group. Speaking of salaries, adjustment according to the expenses of living for the high-expense areas (ex, states of California and Massachusetts) must be mandatory. it is unfair to pay post doc 55K yearly stipend in a city where a studio apartment 20 miles away from his workplace will cost them 30K in rent/year.

Proven or promising external resources or approaches

No response

Response 1969

Perspectives on the postdoc roles and responsibilities

Opportunity to

1. pivot,
2. specialize,
3. bolster resume,
4. last chance to determine if academia is right for me.

Fundamental issues and challenges

Financial compensation for the quality and quantity of work is completely unfair. Many trainees realize this early on and leave academia for this reason. Postdoctoral training is much more stressful than being junior faculty, so the intensity of that experience is self-selecting people out.

Existing NIH policies, programs, or resources

Perhaps write synopses of the PARs in a more user-friendly manner (rather than as a government document). NIA has a blog written by program officers that breaks things down into understandable terms. The problem with the PARs as they are current written is that it reads like a legal document where all things are laid out, but you bury the lead.

The infographics for career paths are nice, but a more comprehensive, interactive, online tool may be more helpful.

Proven or promising external resources or approaches

European and Australian postdocs (and graduate students) seem to enjoy life more and get paid more. There could be some lessons gleaned from other systems.

Response 1970

Perspectives on the postdoc roles and responsibilities

The postdoctoral position should be an opportunity for the scholar to gain deeper training in their area of interest. This should not simply be a continuation of your work in graduate school, but build meaningfully on that training and endow you with the skills necessary for success in the next stage of your career. It should be supportive of trainees headed to research-intensive faculty positions at universities and colleges, but also of trainees headed to different areas including teaching, industry, and elsewhere. Postdocs should have more independence than graduate students, and be supported in developing specific interests particular in the second half of the postdoc (e.g. projects that will support independent research after the postdoc lab).

Fundamental issues and challenges

Pay. Postdoc salary can be hard financially (especially with kids), and hard to justify through the many years it takes for a successful postdoc in my area of research. This might have been more acute as a first-generation college student, but it also might be felt by most postdocs (but I remember my brother asking me, "If you have a PhD, why do you still make so little?"). Leaving my postdoc for another job that would pay twice as much was always in the back of my mind, even though my career goal throughout my postdoc was to obtain a tenure-track faculty position. Better support for parents is also needed. Another major concern is weighing the value of a postdoc—for a student interested in pursuing academic research, it's no secret how hard it is to get good positions now. Seeing that competition for faculty positions (who doesn't know an absolutely stellar postdoc that struggled and failed to land a faculty job in their first, and even second year trying?), and thinking about spending 4-8 years in a postdoc, I would definitely think very hard before starting a postdoc if I were graduating now. Students also sometimes say don't want their PI's job "because they want a life". This can be interpreted several ways, but when I have heard this, I think it comes from wanting a good work-life balance. Graduate students now don't all want to work on the weekends or evenings, but they see us doing that, and I think it's fair to not want to sign up for a career where that seems expected. I am not fully sure how to address this; as a new faculty member I do feel like I need to work weekends and evenings, often, to keep up.

Existing NIH policies, programs, or resources

Increase the recommended minimum postdoc salary, and increase raise percentages with each year as a postdoc. Track postdoc career trajectories, and make this data easily found so students can better inform their decision to pursue a postdoc.

Proven or promising external resources or approaches

No response

Response 1971

Perspectives on the postdoc roles and responsibilities

Catalyzing future independent investigators to conduct rigorous basic, translational and/or clinical research.

Fundamental issues and challenges

The traditional postdoc structure and associated salary is no longer sustainable with maintaining an adequate quality of life. Graduate students, like myself, can no longer maintain a positive outlook or quality of life following graduation if entering a traditional postdoc. Industry opportunities are simply the more lucrative decision now, especially if one wants to raise a family. The postdoc crisis exists for several major reasons: salary that is unsustainable for adequate living, not enough jobs, and limited support for ESIs pursuing extramural funding.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 1972

Perspectives on the postdoc roles and responsibilities

The postdoctoral position is an avenue to continue training via a few strategies:

1. gain additional training in necessary skills for transitioning to research independence;
2. have protected time to increase publication/presentation record and collect preliminary data for establishing research independence/developing a career-development grant application. The postdoctoral position also offers additional opportunities for networking, time to interview for faculty positions, and ability to exercise preliminary research independence without the additional pressures of being on faculty.

Fundamental issues and challenges

The main issues are: low pay (particularly that is not commensurate with cost of living: for example, $53K goes a further in North Carolina than it does in San Francisco), poor insurance coverage, and poor time off/parental leave. Many postdocs are getting married and/or starting families during their training, but struggle to have time off to go on honeymoons, spend time at home after birth of a new baby, or financial ability to afford feeding, diapering, clothing, childcare, etc. for children —particularly in areas with higher costs of living. This is especially relevant for female childbearing postdocs who have little to no time to recover or bond with their babies. For female postdocs who experience difficult pregnancies, this may result in much time off without pay. Lack of time and money results in many postdocs delaying families, leaving postdoc to start a family, and/or living with anxiety over making ends meet and caring for children.

Moreover, health insurance for postdocs is subpar. For major medical emergencies or postdocs with medical issues requiring regular physician visits, many postdocs would/do incur large medical bills. Combined with low salary, it is not feasible for many to enter into a postdoc when industry careers offer better benefits and significantly more pay.

Finally, low availability of money for reimbursement for travel to conferences and many forego some networking/research presentation opportunities due to inability to afford the unreimbursed travel.

Existing NIH policies, programs, or resources

Allowable training-related expenses should be expanded to include additional travel costs. For example, my training grant only allows $2000 for travel to the NRSA trainee research conference. First, $2000 is maybe the cost of a hotel and flight in today’s economic climate. Secondly, that limits my ability to attend national conferences in my research field because I cannot afford the costs. Meanwhile, there is the extra

"training-related expenses" budget that I am unable to use for travel despite it being a necessary and beneficial part to my training.

The ability to offset childcare costs via a $2500 stipend is incredible. However, again, cost of living and cost of childcare across the country is vastly different. This should be taken into consideration when determining the appropriate stipend level for childcare.

Stipend levels should be altered to be commensurate with cost of living and inflation.

Proven or promising external resources or approaches

Working with insurance companies to alter the coverage for postdocs will be invaluable and reduce stress surrounding medical needs. Working with institutions to improve leave policies, particularly parental leave, will also be beneficial at improving morale.

If the postdoctoral benefits can be more commensurate with what will be offered via industry jobs, it may be easier to recruit and retain postdocs who are interested in academia but cannot afford the low benefits PLUS the low wages. Of course, NIH will not be able to provide the same level of benefits as industry jobs, but commensurate benefits and salary coupled with the excellent additional training may be able to entice individuals to remain in academia for a few additional years.

Response 1973

Perspectives on the postdoc roles and responsibilities

Initially when one starts his/her Postdoc, every one want to grow in Academia, But eventually, the interest fades away because of environment and the conditions most of the PI create in the lab.

So my perspectives how postdoc should have been is totally different than what i see now.

There should be proper regulated system.

Fundamental issues and challenges

The Fundamental issues and challenges in the postdoctoral recruitment is the salary and time wastage because the Principal Investigators don't publishes till they grants funded for that particular project.

Though there are many challenges, like postdocs are expected to provide more efforts and being paid less. This is one of the fundamental issue. Another important issue is the unmet promises from the PI's to the postdocs especially, the longways to jump to the next level of their career.

Another thing i would like to mention is that I am almost in the 8th year of my Postdoc and i am now getting $54000 annually. In particular the PI's at [redacted for anonymity] pays very minimal salary (epecially at Department of Pharmacology and Regenerative medicine).

Existing NIH policies, programs, or resources

I don't think existing policies are balanced as we see very high bias interms of postdoc fellow recruitment. For example, in one particular department one PI pays to his/her according to the rules but at the same time others don't follow.

I would like to mention to the NIH that the rules for postdoctoral recruitment should be modified and this should be regulated by some committee which is under the direct control of NIH.

There should be proper Basic Minimum of salary amount which a postdoc should get and importantly, there is be defined increase every year irrespective of the Institution, lab or the Principal Investigator.

Proven or promising external resources or approaches

I can only say some PI's are really mentors, otherwise PI's kill the career of their postdocs rather than developing it.

Response 1974

Perspectives on the postdoc roles and responsibilities

A postdoc is where you receive training to develop skills and confidence to become an independent researcher. You receive training on grant writing and grant thinking. Guidance from your PI to apply for pilot studies and develop them into training grants and R01s. You develop your teaching portfolio and build connections with program officers.

Fundamental issues and challenges

No response

Existing NIH policies, programs, or resources

More free NIH grant writing workshops. Networking opportunities with NIH PD and POs. Grants and financial support for joining research organizations such as SER, AACR, APA, and ISEE. Opportunities to review grants.

Proven or promising external resources or approaches

Peer mentoring/matching programs

Postdoc retreats to exchange ideas and share experiences

Writing training

Course development training

Time management skills and tools

Response 1975

Perspectives on the postdoc roles and responsibilities

Incredibly valuable for post docs, research teams, academic environment and broader work force.

Fundamental issues and challenges

I have directed a post doc research training program for 20+ years. Over the last few years there has been a clear decline in number of applications. I don’t know why this is but suspect it is due to the intense competition for subsequent positions. Perhaps this is a problem that is self-correcting. But clearly in order to increase recruitment/application we need to increase the likelihood of success post training. That is a complex set of factors that there is not space to address here.

Existing NIH policies, programs, or resources

I think the issue is not inherently within the post doc training programs but post training (as above).

Proven or promising external resources or approaches

Increase time of post doc. Our program is two years. I think three years would decrease pressure on trainees and better prepare them for subsequent experiences.

Response 1976

Perspectives on the postdoc roles and responsibilities

Envision and execute scientific project; train in new technical and leadership skills

Fundamental issues and challenges

Low stipends; bad environments with little accountability of mentor abuse of power

Existing NIH policies, programs, or resources

Higher NIH stipend levels at least consistent with the NIH intramural pay scale

Proven or promising external resources or approaches

No response

Response 1977

Perspectives on the postdoc roles and responsibilities

The academic postdoc is a dedicated time to conduct research and build a research program. While there is a little mentored training in the first year or two of the postdoc, the postdoc position is primarily a time to conduct independent research that benefits the lab and the university.

Fundamental issues and challenges

The fundamental issues facing postdocs is that our salaries and benefits do not match opportunities outside academia. In recent years, our salary has not kept up with the rising cost of living due to inflation. Additionally, many postdocs are starting families, but our salary/benefits are not sufficient to support them. As highly trained individuals in our 30s-40s, we do not make enough to save for retirement. These problems, combined with the uncertain time period that a postdoc position often lasts, are driving individuals to leave academic research. Additionally, the lower income that postdocs receive are driving individuals from lower socioeconomic and historically under-represented groups to leave at a higher rate.

Existing NIH policies, programs, or resources

The current career development awards should be expanded to include more opportunities for late-stage postdocs and individuals from historically under-represented groups. The existing eligibility window for the K99/R00 is ridiculously short as it discriminates against individuals with families, medical issues, or COVID-related disruptions. The prior extensions to the eligibility window for COVID were not sufficient and ended abruptly. There needs to be multiple grant opportunities and funding sources to support postdocs transitioning to faculty positions as well as to postdocs transitioning to non-tenure track positions.

Proven or promising external resources or approaches

No response

Response 1978

Perspectives on the postdoc roles and responsibilities

A postdoctoral position means moving to a new location for a temporary position and continuing to do the same work as grad school.

Fundamental issues and challenges

Pay is barely over the graduate stipend when health insurance costs and taxes are accounted for and far less than industry. Because the goal of most postdocs is to get a job that requires moving again, it’s hard to feel settled

Existing NIH policies, programs, or resources

The stipend needs to be increased. Additionally, PIs need more training on how to structure postdoctoral fellowships to be completed in under 5 years and end in the successful placement of the postdoc in their desired career

Proven or promising external resources or approaches

More professional development opportunities, time limits of postdoctoral fellowships, yearly check ins with additional faculty

Response 1979

Perspectives on the postdoc roles and responsibilities

I view post-doc position to develop additional technical expertise and explore challenging research questions more independently but also receiving support from mentors. Unfortunately, many postdocs are just left on their own to survive without much support in training and development.

Fundamental issues and challenges

Mentors don't take post doctoral scientists very seriously specially when they are from minority. There is no accountability of why a certain postdoctoral scientist was not able to publish. Was it the advisor's fault who are busy continuously building their careers. Lot of racial discrimination happens. Secondly salaries are the lowest for individuals with the highest degree. People actually say that you should focus on training and not money. However that is completely wrong because you have already spend so much time in school and with no prospects of job or financially stable future, results in depression, lack of motivation and desire to do research.

Existing NIH policies, programs, or resources

Lot of higher education has people who are international students and they are not allowed to apply for certain grants then automatically their resume wont stand out.

Again lot of weightage is given to people who have list of accolades. During my time in academia, I observed all these awards such as AHA and conference talks are determined by who is their advisor. There was no outcome from the research as the winner never really worked on the project but having the award boosted their resume to get more recognition.

Mostly people are only working to build their careers and not to continue research.

Lot of it depends on the advisor and not the student. Which is complete unfair advantage.

Proven or promising external resources or approaches

1. Improvement in salaries, most US undergraduates make more in industry than postdoctoral scientists. This is completely demotivating and shows there is no value in doing basic research which is the fundamental in generating IP.
2. There is a strong inclination towards studying only translational science.
3. Putting emphasis on publication than intellect as a judging factor of students merit.
4. Unsaid racial discrimination.

Response 1980

Perspectives on the postdoc roles and responsibilities

The postdoc position should provide adequate training in becoming an independent scientist. This includes grant writing, project design and implementation, and mentorship. The lack of uniform training of these things at the postdoc level is apparent and needs to be promoted regardless of subsequent career path.

Fundamental issues and challenges

Given the competitive nature of the academia, post-docs are inherently required to work long hours to even have a chance at success. The high-stress, long-hours, and minimal pay discriminates against many who are more than qualified, including those who have or are wanting to start a family. Increasing the institutional minimum salary set by the NIH and providing better benefits is an absolute must if recruitment and retainment efforts are to be improved.

Existing NIH policies, programs, or resources

Given the minimal faculty positions available, one could argue that the NIH is currently supporting to many post-docs. One way to potentially increase the post-doc salary is to simply put a limit of the number of post-docs a lab can have. Perhaps this limit is even applied at an institutional level. This may "re-invent" the process of procuring a post-doc, having a more generalized application system, like is done for graduate school.

Proven or promising external resources or approaches

No response

Response 1981

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

Salary, options following a postdoc are slim, most industry doesn't require papers or much of a postdoc if any

Existing NIH policies, programs, or resources

I don't think NIH is the problem. Generation shifts and the complicated nature of getting to tenure these days is the problem. The bar is so high that only those who are truly exceptional and work 24-7 can tread water. Students don't want to work even 40 hrs per week, so a postdoc or PI position is no value to them. The next generation is in it for the money, and there's no money in science

Proven or promising external resources or approaches

Faculty positions are the problem, not postdoc, which causes the lack of postdocs. It's becoming extremely challenging to get a PI position and become established to tenure. It's more competitive and the bar is very high, and academia is not supporting sufficient funds to run and staff a lab, R01s are not enough and get cut often. The next generation wants work life balance that is not conducive to most biomedical science roles.

Response 1982

Perspectives on the postdoc roles and responsibilities

I believe that post doc training should help nurture a fully independent scientist for the type of role they would like to pursue in the future. There should be some scientific training as well so that the scientist can learn new and pertinent techniques, but the focus should be on preparing the individual to write grants, manage people, manage time and projects, and to conduct great research.

Fundamental issues and challenges

In academia, there is a focus only on academia. No training for industry positions is available. The academic advisors are not trained in management skills and do not provide psychologically safe workspaces (this goes for doctoral training mentees/PIs as well). They take their stress on grant writing out on their post docs or trainees. They still berate people in front of other coworkers. There is zero work life balance and zero HR protection. There is zero vacation. There are extremely high expectations and pressure with little pay. You can easily move to industry and make 3x the money in an industry post doc. In industry, management is required to take managerial and psychological safety training as well as harassment training. Tenure does not protect people if they participate in bullying behaviors in industry but it does in academia. There are little benefits as an academic post doc and the pay doesn't match inflation. You can hardly afford to live on current salaries and if you have a family there is no way you could afford daycare. Why would anyone want to work in this environment when they can make a more direct impact on patients by working in industry while having better workplaces/benefits/safety. The entire academic tenure system should be overhauled. It is difficult to get grants and we see how it affects our mentors and we want to leave. It's not a good system.

Existing NIH policies, programs, or resources

Required management training for mentors

Required psychological workspace training for mentors

DEI and harassment/bullying training

Better pay and better benefits

Vacation time and sick time

HR requirements

Proven or promising external resources or approaches

Response 1983

Perspectives on the postdoc roles and responsibilities

1. Opportunity to share and teach knowledge about research, writing grants and papers, presenting, and some effort on teaching. During meetings, introduce the postdoc to many local, national, and international colleagues.
2. Should be viewed as someone qualified and relatively independent with limited supervision and more assistance focussed on what would best benefit the postdoc.

Fundamental issues and challenges

Traditional job prospects are very limited, and we must be more honest about that.

Difficult to recruit in smaller, not as well-known colleges or universities.

Politics get in the way these days when trying to locate and convince the best applicants to join the team as a postdoc.

Existing NIH policies, programs, or resources

More programs that facilitate the transition from postdoc to junior fac.

Though, from experience, when a postdoc gets a K99, then he wraps up the project and is often immediately recruited by another "bigger/better" university that loves these applicants as they arrive with their own funding. Be creative to find a way to protect this exode of K99 awardees (in which the mentor spent a lot of effort). Find incentives that maybe a 50K be given to the current Dept if they can recruit that person (and that 50K would not be available if the applicant goes to another institution. It is even more difficult in clinical departments to commit to such recruitment (so there is no incentive at the end for the mentor to do these K99-R00.

Proven or promising external resources or approaches

Improving National and International Recruitment maybe with a central repository of open positions (for free).

Response 1984

Perspectives on the postdoc roles and responsibilities

Post docs are severely underpaid. Please do something. There scarcity of smart people in academia will be the prominent otherwise.

Fundamental issues and challenges

Extremely low salary.

Response 1985

Perspectives on the postdoc roles and responsibilities

Postdoc is supposed to be a training position where Postdoc receive academic training to prepare him/her for next level in career.

Fundamental issues and challenges

Postdoc nowadays suffer from many difficulties and hardships starting from low salary compare to working hours and whether enough to cover a small family expenses to poor monitoring by PIs. While this position in essentially important for advancing science in all fields, those trainees (postdocs) are not treats equal to their effects and they are not well protected against PIs power over them especially that most of them are international who are in USA on visas.

Many freshly graduated PhDs try to avoid going through postdoc positions because they don't want to spend several years earning little money (most times not enough to survive) and not getting enough support by their monitors to progress in their career.

Existing NIH policies, programs, or resources

Most important is to monitor PIs activities because most PIs are selfish and intentionally blocking their trainees which is the opposite of their proposed role as PIs. Please, watch PIs' behaviours closely and request school/departments to follow on how PIs-Postdoc relationships are going from the start through toward the end of the proposed training. Most of the time, postdocs are the loser side and this produce bad reputation where newly graduated PhDs who will decide not to do postdoc but to join industry instead.

Proven or promising external resources or approaches

I think, as someone spent many years in postdoc training who wished to have good transition to faculty position, the most difficult part is dealing with PIs during training. I worked with couple of them and they share same bad attitude that should not be in a person who serve as academic and should set as a good example. NIH needs to work closely with schools/departments to help in improving the outcome of postdoctoral training and make sure they are not just used to make PIs only successful.

Response 1986

Perspectives on the postdoc roles and responsibilities

I view a post-doc as a known stepping stone towards academia and continuously refining the research interest, techniques, scientific thought and direction of the field for faculty positions. However, I also feel this is a laborious undertaking that does not pay for the quality of work demanded, treatment of the stature "post-doctoral" and lack of sustainability given the diverse set of graduated individuals from many PhDs. I am an undergraduate seeking to consider this route, but financial security will always be priority.

Fundamental issues and challenges

The most obvious one is pay. How can one claim to be an independent scientist, fully-trained yet his/her/their value is worth at a bare minimum, "not much more than" a PhD stipend? Especially, given that the industrial life is much more appealing financially but also academically in some sense too—it just does not seem like a great investment. It's not only the funding that I see is an issue, it's also this old-school culture of "publish or perish" and to join the best of the best labs for the sake of prestige. This does not push science forward. This limits science. Especially by those in marginalized groups that are being brought into the academy and expected to survive by the traditions of "it is the way things have been" and yet, systemically and historically, have favored a group more so than the others. The richness of a postdoctoral training does not mean we should devalue of a person. And that is increasingly more true if the cost of living does not reflect the salaries. Let's start reforming old practices and push science forward by adapting the old ways of post-doctoral academia.

Existing NIH policies, programs, or resources

Please consider the following below in the way we think about the ecosystem:

https://journals.plos.org/ploscompbiol/article?id=10.1371/journal.pcbi.1009313

Response 1987

Perspectives on the postdoc roles and responsibilities

A postdoc position should only be training to step into an independent role. However, many principal investigators view it as a position to help their lab and their career, with minimal or no grooming of the postdoc to be independent. On contrary, some PIs make sure that the postdoc remains in the position as long as can be stretched and when the time limit is reached, they try to leave them helpless to struggle with their career.

Fundamental issues and challenges

1. PIs who are not interested in development of other people careers and merely care about their labs
2. Very low income and bad health insurance coverage for postdocs
3. Nepotism to retain people who butter the PIs ego and not to retain those who are rational thinkers. Opinionated postdocs are at the risk of being fired if their ideas are better than a PI. There is no way to let postdocs think and work freely.
4. PIs who are toxic and discriminating to the postdocs are threat to the science.
5. No conflict resolution or ombudsman to handle toxic work environment.
6. Stepping into a career which may not land anywhere in the future, leaving postdoc and their families stranded in tough situations. All their years of training is wasted as a result of poor retention in academia.
7. Often departments hire postdocs from big lab (nepotism) because they know their PIs. No equity standards in hiring process
8. Often departments have someone whom they want to hire even before they post a faculty position

Existing NIH policies, programs, or resources

1. NIH must have a means to measure the PIs capacity to supervise a project. Some PIs are not intellectually able to train a postdoc due to lack of experience in their field. If you refute a PIs idea even if it not backed by scientific hypothesis, they may perceive it as rude behavior and the postdoc may face threat to their career as retaliation from the PI.
2. NIH must have a website where postdocs can rate a principal investigator. This way prospective postdocs will have the means to check if the PI has a good or bad reputation with other mentees.
3. NIH must have a confidential website to report any kind of discrimination and must support postdocs who are victims of such abuse. I was one of the victim, but the institute where I worked didn't take any step to ensure PI is investigated because the PI was a clinician who more necessary for the hospital than a researcher
4. Institutes favor clinicians over scientists.
5. NIH must make it mandatory to hire people without professional references. Professional references from a PI who is bad to the postdoc won't be fair portrayal of the postdocs ability. If NIH wants to keep the professional references then it should also be mandatory for a PIs promotion. PIs must need a reference from their postdocs for their assessment as a PI. There should be some way to have a 2D referencing systems, which means PI writes reference for postdoc's future jobs and postdoc should write a letter for PIs promotions. This will ensure no PI intentionally holds a postdoc for an infinite time and also ensure the postdoc is not unfairly treated
6. All the references should be visible to both parties. Professional references should not be confidential.

Proven or promising external resources or approaches

1. NIH must make it necessary to provide a report for past postdoc recruitments as a section in PI's R01s. This section should also be scored and must be used to decide on future funding or R01's outcome
2. NIH must make a website with PI ratings, so that no future postdoc has to go through the same rude behavior from a PI
3. All the postdoc trainings must directly be funded by NIH, so that the PI doesn't blackmail the postdoc to fire in the middle of postdoc position
4. Postdocs must get same salary and must get chance to present their work every 6 months at their host institute. Often PIs present the work and postdocs don't get chance to present their own work

Response 1988

Perspectives on the postdoc roles and responsibilities

Postdoctoral training is meant to be a continuation of the training that you received in your PhD. However, instead of the technical skills, I think that postdoctoral should entail more leadership training and responsibilities, regardless of whether the individual intends to continue in academia. For those who are intending to continue in academia, it is the place where you also develop your research program and identify your niche within your chosen field.

Fundamental issues and challenges

Many institutions do not have formal support for postdocs, which stand in stark contrast to graduate or faculty support. In many institutions, postdoctoral fellows fall in the cracks as there is usually not a formal office set-up to provide them with formal support. At the same time, this lack of organization means that there is also no social support for postdocs, many of who travel far away from their social and family circles and can feel very isolating. In addition, for non-US citizens/residents there are very few opportunities for funding application, and instead rely on private funding sources which are often extremely competitive, and the availability can vary greatly depending on your chosen field.

Existing NIH policies, programs, or resources

Additional funding opportunities for non-US citizens for all postdocs at various developmental stages (ie. both early and late stage postdocs) would serve to provide more training opportunities for postdocs seeking an academic posting. At the same time, it would help to have formal training sessions for skills that are expected of individuals who want to run their own research lab but are generally harder to develop (ie. budgeting, grant writing).

Proven or promising external resources or approaches

No response

Response 1989

Perspectives on the postdoc roles and responsibilities

This should be an opportunity to focus-in on research topics to lay the foundation of the rest of your career. However, we (postdocs) perform the experiments, collect and interpret the data, and make the discoveries that end up boosting the career of the PI and of the institute/university much faster than our own careers, and for minimal compensation relative to the amount of work/findings we contribute. Where would the PI or the institute be without the researchers?

Fundamental issues and challenges

Salary is embarrassingly low for the amount of experience we bring and the amount of work we do (not to mention the amount of educational debt we accrued to get to the postdoctoral position). I love my research, but cannot support my family on this salary and will be seeking industry employment sooner than originally planned to get compensated appropriately for the tireless hours I spend doing research. Just a single example: with such a low salary, especially with today's exponentially increasing cost-of-living, we cannot afford nice housing, which cascades into endless home repair projects that we must DIY

because we cannot afford to hire help. This takes away from time working/focusing on research and prevents any possibility for free time or much-needed rest. This all results in faster burnout. With appropriate compensation, we could hire help (for home care as well as child/family care) and improve morale drastically. The status as a "trainee" is also very difficult for postdocs in mid-late 30s (most of us): we are not eligible for retirement contributions or other benefits offered to "actual" employees. We are too old and experienced to be treated like young people with no outside responsibilities.

Existing NIH policies, programs, or resources

Honestly, increasing salaries to compete with full-time jobs is the number 1 issue. Many of my fellow grad students skipped the postdoc position to take real, full-paying jobs for the money standpoint alone. We help submit substantial grants for research funding, yet so little of that money directly supports the individuals that make scientific discoveries possible.

Proven or promising external resources or approaches

No response

Response 1990

Perspectives on the postdoc roles and responsibilities

My current postdoc position is offering me learning opportunities to built new skills, project management skills and team work. The learning opportunity by participation in conferences and workshop is helpful in career development.

Fundamental issues and challenges

- I believe the biggest challenge is that the postdoc stipend is very less and is not adjusted for inflation over the years.
- The second challenge is visa options for visiting fellows. NIH-funded postdocs have 212e section on their visa which requires a 2-year home residence. No such policy exists for fellows pursuing their postdoc in Canada/Europe/UK/Australia and hence makes those destinations more desirable for prospective postdocs, and this will impact the US postdoc diversity in near future. Beside 212e, the visa sponsorship is short (1-2 years initially and renewed annually) and for visa stamp renewal one has to go back to their home country and this whole scenario limits participation of postdoc fellows in international conferences/workshops.
- No relocation allowance for postdocs especially those who relocate from outside USA.
- No affordable childcare policy
- Lack of remote work opportunities
- No subsidized housing options (postdoc salaries are not enough to cover rents in this inflated market and it pushes postdocs to rent room in shared houses)
- No pension plans for postdocs
- Maternity/Paternity leave policies are not good
- Gender bias
- Lack of framework for non-track tenure positions

Emphasize on career opportunities after postdoc training

Response 1992

Perspectives on the postdoc roles and responsibilities

Additional training period for highly skilled academic-bound scholars. Employees are appointed with substantial freedom to learn new skills toward managing their own labs and pursuing unique directions for their own future research programs. Responsibilities include assisting with lab and project management and student mentoring with the support and direction of the lab PI. The appointment should not proceed for an indefinite period of time. Outcomes and career goals should be mutually agreed upon at the beginning of the appointment, and the lab PI should be supportive of the postdoc to the fullest extent of their capabilities. This includes letters of support submitted in a timely manner pursuant to application deadlines, etc.

Fundamental issues and challenges

Fundamental issues that I foresee are, primarily, lack of competitive and adequate salary support. Lack of familial support. Other possible issues might include indefinite training periods and lack of PI career support.

Existing NIH policies, programs, or resources

I think the NIH needs to increase minimum salary guidelines. Many PIs use this as a benchmark for establishing postdoc salaries and it’s simply not adequate enough for the level of existing skills that they contribute to the laboratory ecosystem.

Proven or promising external resources or approaches

NIH-sponsored mentoring of postdocs, I think, might help to supplement lab PI mentoring and experience. Conferences and other scholarly events would help to inform postdocs and hiring institutions of potential job candidates. Monetary support for conference travel for postdocs who have not secured or are ineligible for fellowship support would help postdocs pursue academic positions and help alleviate the monetary burden to the PIs.

job satisfaction

Response 1994

Perspectives on the postdoc roles and responsibilities

I personally view the role of being a post-doc in academia as an opportunity to further my training and skills gained during my graduate program, acquire new skills in both benchwork and writing and make concerted efforts to move into an academic position to satisfy my intellectual curiosity and also benefit the research community at large by helping excel the careers of people working within the academia, especially from underrepresented backgrounds, by constantly advocating for their rights and creating an equitable atmosphere to support them.

Fundamental issues and challenges

The most significant issues and challenges in this regard are:

1. Non-uniform and mostly lower than average salary.
2. The nature of the job itself where one ends up working 7 days a week (usually on writing on the weekends) which leads to poor work-life balance, poor quality of life and burnouts.
3. Lack/scarcity of funding opportunities for post-docs which leads to disappointment and severely affects passion and motivation in the long run.
4. Exploitative PI centric atmosphere, especially for international fellows, where PIs lack accountability to higher authorities altogether regarding the overall career graph, wages and treatment of the fellows.

Existing NIH policies, programs, or resources

1. Uniform salary policies dictated directly by NIH which are not subject to modification by institutions/ PIs.
2. Creation of more funding opportunities for international post-doctoral fellows, since international fellows constitute the largest fraction of post-docs in the Unites States, most of which are forced to move out of academia after 3-5 years of post-doctoral training when they are not able to score funding for themselves. This, to me, is the biggest impending factor for retention of post docs.
3. Post-doctoral training expectations and consequent burnouts affect women post-docs the most in terms of retention, since most of them are not able to meet the requirements of this role while managing a family and raising kids. Creation of more hybrid (Teaching /research) positions in colleges and universities, with special preferences for women post-docs should tremendously affect retention.

Proven or promising external resources or approaches

A large number of postdoctoral trainees have moved, and many are planning to move out of academia to industry for primarily three reasons:

1. Better salaries
2. Better hours and less stress/burnout
3. Growth directly related to productivity.

If NIH is able to deliver on at least one of these criteria to begin with, retention would significantly increase. Putting endless number of hours in writing a paper/grant application with a failure rate of more than 90% is a very stressful situation and is something that has come up in discussion within the post-doc community across US as one of the biggest reasons for switching field.

Response 1995

Perspectives on the postdoc roles and responsibilities

Advance science while receiving training to move career forward.

Fundamental issues and challenges

Compensation does not match cost of living.

Existing NIH policies, programs, or resources

Salary limits should be removed and post-docs should be able to negotiate salary based on training and productivity.

Proven or promising external resources or approaches

No response

Response 1996

Perspectives on the postdoc roles and responsibilities

I was excited to take on an academic postdoc to continue my growth as a researcher, and to develop some independent research skills so that I could pursue a position as a PI and researcher. I'm currently in a T32 fellowship. Unfortunately, what I have learned is that jobs do not exist for this career, and so my postdoctoral fellowship will likely not help me move into that role (because there isn't one!). Addressing this at fellowship doesn't make sense. There need to be more changes upstream first. There need to be more academic jobs available, more opportunities available at that level, and then post-docs will become popular again.

Fundamental issues and challenges

1. Student loans: As clinical research programs shift to not being funded, it is challenging to pursue academic research. I have 300,000$ of student loans, and I make ~50k this year as a fellow. I think it's hard to choose this life when a significant portion of my salary has to go into student loan payments. If I go into academic research, how can I make these payments and also survive? It's tough, and I wish NIH was doing something about it. Even LRP, if I were to get it, would be a tiny drop in the bucket. It's hard to consider staying in this world when it's not financially feasible.
2. Salary: It is truly appalling to work for so many years to receive such a paltry salary at this state of training. I have been in graduate training since 2016. When applying for postdoctoral fellowships to start in 2022, I considered taking a fellowship in private practice which offered better benefits and an 80K starting salary. It was a significant sacrifice and has negatively impacted my quality of life to take a fellowship in academic research over one in private practice.
3. Job security: In spite of working tirelessly on fellowship (the capstone of many years of tireless work as a graduate student), jobs for me may not exist. They may not meet my needs, they may not pay well enough. Institutions have all the power, and we have none. In light of this, it feels like it makes sense to jump ship sooner rather than later. Trainees are not respected and the paucity of jobs in research make it feel like we are jumping through hoops to end up in a fire anyway.

Existing NIH policies, programs, or resources

LRP should be significantly more and younger trainees should be prioritized for receiving this grant. This might incentivize more people to pursue and stay in academic research (If NIH was taking care of my loans, I would be delighted to commit to staying in research!) More time to do a K and being able to have a virtual mentor rather than getting it through a specific institution—many institutions won't even give you the opportunity to apply for a K and, if you're in a specific field, there may only be a handful of mentor options who could support you, and if that institution doesn't hire you, you are unable to apply for these training awards. The salary should be increased dramatically. Additionally, there should be a commitment on the part of NIH to try to help us find and land somewhere that will encourage our research.

Proven or promising external resources or approaches

Again, this pathway is not financially feasible. NIH can say all it wants about supporting postdoctoral fellows, wanting to encourage research, DEI, etc. But many people will never be able to take on these kinds of paths due to the financial difficulties they create. I am a child of immigrants and put myself through college and graduate school because I desperately wanted to do this work. After over 10 years, I've finally acknowledged that I can't sustain this. It's heartbreaking, and I do really wish NIH was more responsive and had more programs for loan repayment on a larger scale. (Even things like taking care of our student loans payments while we're on fellowship would make a MASSIVE impact!)

Response 1997

Perspectives on the postdoc roles and responsibilities

The academic postdoc is essentially a PI in training. This means that they are not just independent scientists driving forward research projects in innovative and collaborative ways, but also mentors to their colleagues who are in earlier stages of their research career (e.g. graduate students, technicians, and even undergrads). They are a key element to the lab in that they bring their own expertise and training obtained throughout their PhD journey to the lab and can share that with the other lab members. I see a postdoc as a role model and a second, perhaps day-to-day, mentor aside from the PI. In larger labs, they are a critical component of the graduate student learning and training experience when the PI is more absent or busy. They also help shape the culture and environment of the lab and have major influence on workplace interactions and the ultimate directions of a lab.

Fundamental issues and challenges

Pay is a critical element here. Given the responsibilities and roles I highlighted above that postdocs often take on in a lab, and considering the fact that they do, in fact, have a PhD, academic postdocs are paid far too little for all the work that they do. Besides this, the academic postdoc usually makes below the livable wage for the city they are located in, especially in places where the cost of living is becoming astronomical. There is also a lot of insecurity regarding when an academic postdoc will finish their time in the lab and when they have published enough. With fewer tenure track positions available, competition for those jobs requires a postdoc to practically eat, sleep and breathe their research, with little room for a work-life balance or personal goals. When is it enough? Along with pay, lack of proper benefits is also critical. Many postdocs are in committed relationships or are even parents who need access to adequate and affordable childcare, healthcare, leave of absence policies, and healthcare. A postdoc often makes too much to qualify for government aid like EBT/food stamps, but not enough to meet the increasing global inflation and cost of living. Finally, a lack of diversity in academic leadership, funded PIs, and departments is a major driver of decreased recruitment and retention of diverse PhDs into postdoc positions. As a grad student considering a postdoc, it is really discouraging to look around and only see the same kind of people in academic positions of power and decision-making: older, white men whose experiences in science largely do not match the dynamic changes occurring both in the scientific community and the United States. Our generation's challenges are simply being overlooked and often ignored.

Existing NIH policies, programs, or resources

Increased K99/R00 funding for postdocs from smaller, non-RL-1 institutions would be a great help in securing positions. An expansion of the recently developed NIH F99/K00 fellowships for graduate students would also be a major support for students who are seeking postdoc positions in various fields of research. This would mean extending the F99/K00 program to other branches of the NIH besides the ones currently participating. Adding/expanding requirements for DEI training within NIH-funded academic institutions and incentivizing recruitment of scientists from diverse backgrounds, research fields, and institutions would also allow for increased diversity among postdocs, and ultimately, principal investigators. Reforming the academic tenure system within NIH-funded institutions and implementing newer, stricter guidelines for who gets tenure would also be really important. For example, a professor seeking tenure should be required to provide substantial proof of their efforts in fostering diversity beyond just sitting on a DEI committee or hiring diverse scientists. That way, more professors who are truly committed to DEI efforts will be in decision-making positions.

Proven or promising external resources or approaches

The industry model for postdoc recruitment is a great example of what kind of pay and benefits postdocs should be receiving. In addition, following closely the fluctuating and ultimately increasing costs of living surrounding each NIH-funded institution and implementing baseline guidelines for adequate postdoc compensation in accordance with these costs would be helpful.

Response 1998

Perspectives on the postdoc roles and responsibilities

The postdoctoral role seems to be a required step for advancing an academic career and being considered for either tenure-track or non-tenure track positions. It is a time to publish research, and learn how to run a lab, and demonstrate skills. It is also an opportunity for the postdoc to disseminate knowledge and research protocols between the institutions where he/she has studied so that both institutions can grow together in performing better research.

Fundamental issues and challenges

We need stability. Salary is often mentioned, and would be helpful, however I think it more important to re-envision the postdoctoral position as a 3-year position instead of a 2-year position. Unless there are no setbacks encountered at all, two years is not enough time to develop the independent research foundation that is required to be considered for tenure-track at universities. We spend two years feeling like our job is tenuous, trying to reassure our families, while knowing that we could have no job at all in a very short time due to delays beyond our control. We need stable positions and more funding opportunities designed specifically to support postdocs that are available to both institutions and individuals. This is even more important considering that often universities require applications for employment to be sent in the fall, so that a postdoc has had at most one year to prepare proof of independent research. I find this to be the biggest failing of the postdoctoral position. Rather than giving enough time to develop our career, we must still rely on networking skills who gets the best mentor recommendation letter to advance to the next stage.

Existing NIH policies, programs, or resources

Funding opportunities that are designed specifically to support postdocs need to be expanded so that both institutions and individuals can be simultaneously seeking to provide stable employment. Stability is paramount.

Proven or promising external resources or approaches

The ecosystem must provide resources and approaches that encompass the next career stage after postdoctoral training. How is the NIH helping postdocs to successfully move to the next stage? Current opportunities are too limited.

Response 1999

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

Temporary visa holders: ID and drivers' license expiration dates dependent on contract and customs stamp, funding for non-citizens, payment (low for families and problematic for J1+J2 where the latter is not allowed to work), benefits for partners and families.

Existing NIH policies, programs, or resources

Response 2000

Perspectives on the postdoc roles and responsibilities

Postdocs play a vital role in academic research but while they are skilled, at the same time we must also consider that they are still trainees who are using this position to build their own future careers. This latter point is often lost in recent discussions focused on skilled workers being underpaid.

Fundamental issues and challenges

There are primarily two issues here:

1. The uncertainty over whether postdocs will ultimately become faculty is putting some off taking this training path. This can be addressed institutionally but graduate students also need training in understanding that this is a competitive career path. Not everyone can "win", but you can't win if you don't try. Acceptance that alternative career paths after a postdoc are not indications of failure and are, instead, viable and good options is really important.
2. The second issue is pay/compensation. Expectations should be realistic, again considering these are training positions, while fair in considering cost of living and that some postdocs will commit to longer periods in the lab than others, making the postdoc position more of a career in itself and therefore more needing of better compensation. But the major problem in pay/compensation comes from NIH policies (see below).

Existing NIH policies, programs, or resources

It is ridiculous, and postdocs are shocked when they find out from PI's, that NIH will not allow cost of living increases to be budgeted for in grants, yet NRSA makes sweeping recommendations for very large increases. To make matters worse, each year NRSA not only recommends 3-4% raises, it raises the base level each year. In effect, this results in an approximately 9% raise per year if pay grades are based on experience. As a result, a grant that is awarded with a Level 0 postdoc is rapidly outpaced by NRSA-recommended increases. Moreover, when a new postdoc joins a lab later in an awarded project, their base 0 pay grade is actually higher than the base 3-5 of the original award, creating massive inequity and unfairness that is not the making of the PI. NIH and NRSA policies are completely out of alignment and unsustainable. The pay/compensation issue faced by postdocs is no the making of PIs (most try to pay postdocs as much as possible), it is the making of the NIH/NRSA disconnects.

Proven or promising external resources or approaches

Solve the pay issue above. Also create more equitable and sustainable funding system so that postdocs have more stability. By that I mean, "fund the investigator" for longer periods and avoid funding a small number of investigators with massive amounts of money (multiple, multiple R01s) that show diminishing dollar-value return.

Response 2001

Perspectives on the postdoc roles and responsibilities

In my view, postdoctoral fellow appointment should be reserved to those who have a genuine chance of successfully competing for a faculty position and being successful in that role. Too often, young researchers are appointed as postdoc who do not stand a realistic chance of ever being competitive for a faculty position. Rather, they are hired to work on sponsored research projects under the false pretense that they are being prepared for an independent academic role. These researchers who may not be competitive for faculty positions should be hired directly as staff scientists, without having to go through 5 years of postdoc. Postdoc positions should be reserved for the most promising researchers and should be highly prestigious positions that are well remunerated and with high likelihood of advancing to faculty positions. There should also be many stably funded scientist opportunities for those interested in research who may not be ready for the tenure track.

Fundamental issues and challenges

Recruitment is very hard because most PhD graduates have realized that a postdoc position is a highly risky path with low chance of landing a faculty position and low pay/benefits. Opportunities in industry have improved and provide alternative career paths for newly minted PhDs. The increase n foreign

postdocs is because, to a large extent, the chance to emigrate to the USA is worth the downsides of a postdoc position for many foreign PhDs.

Existing NIH policies, programs, or resources

Here is an ambitious suggestion:

1. Have an early mechanism similar to K99 to identify promising postdocs who are most likely to advance to faculty careers. Only these "super-postdocs" may continue past their second year, possibly with more generous salary, support and training.
2. Other postdocs who are not selected cannot continue past their second year and can either transfer to academic staff research position or industry.
3. Increase the number of stably funded staff scientist positions.
4. Towards the previous point, there is a need for a mechanism to reduce year-to-year fluctuations in grant funding of individual labs. Labs should be able to "bank" unspent grant funding to create a financial buffer and smooth out grand funding volatility.

Proven or promising external resources or approaches

Response 2002

Perspectives on the postdoc roles and responsibilities

An important transition career to independent research scholar

Fundamental issues and challenges

Limited duration of visa/DS2019 status for non-US citizen, uncompetitive salary for a PhD.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 2003

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

Not providing a competitive salary for scientists with doctoral degrees (or even enough to live in the area of the institution in some cases) and especially not enough to start and support a family. Additionally, the increasing expectations on postdocs to be competitive for faculty positions can leave postdocs at a low paying transition phase for years with no guarantee they will land a faculty position. At least if they were getting properly compensated for their work this would be less of an issue, otherwise it is just another example of academia underpaying for research labor, then complaining when they don't have enough labor and initiating these surveys.

Existing NIH policies, programs, or resources

Increase Postdoc pay, incorporate COLA.

Proven or promising external resources or approaches

No response

Response 2004

Perspectives on the postdoc roles and responsibilities

Conducting the scientific research under guidance of postdoctoral mentor. Do researching experiments, data collection, analysis, report and publication. Training and support graduate students!

Fundamental issues and challenges

1. Very limited fellowship or grants to apply; Rare postdocs mentor group supportive environment
2. Need to renew contract annually or even half of year, under the terrible experience to leave the job under pressure; International postdocs are especially vulnerable to badly behaving faculty because they depend on those mentors for their visas.
3. No supporting medical insurance for Spouse dependent
4. Lower postdoc salary from my institute, moreover, H1 dependent H2 was not permit to work in U.S.A except a few cases

Existing NIH policies, programs, or resources

Except K99 fellowship grants, open more accessible to T32, etc for non-citizens

Proven or promising external resources or approaches

1. Give Postdocs a safer/stable environment to hold their positions when renewing contracts, recommend both hired postdocs and NIH funded lab/PI to report their postdoc hiring recruitment and changes records
2. Having something like an "International early career program" for non-US citizens to apply similar to the Diversity Supplement so that "funding award" can be added to their CV as an accomplishment.

Response 2005

Perspectives on the postdoc roles and responsibilities

Leading a research project, mentoring others, building a future research plan. Should be somewhat independent but still receiving feedback from the PI.

Fundamental issues and challenges

The cumulative low wage from undergraduate student loans, to low pay as a graduate student, and then continued into the postdoctoral position. This can equate to 15 years in which you are unable to save any substantial amount of money. Thus there is more incentive to move to industry instead where you can make 2x to 3x more money from the start.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 2006

Perspectives on the postdoc roles and responsibilities

I view a post doc as a resource for the lab in terms of scientific questions as well as troubleshooting technical issues. They should be a mentor to the graduate students and undergraudates in the lab while not taking over the position of the PI.

Fundamental issues and challenges

Post docs aren't making enough money to live on, especially if they could go into industry and be making almost double what they would remaining in academia. There should also be mandatory 8 week paid parental and medical leave so that PI's can't deny this leave or not pay them during that time. In addition, the rising costs of living expenses and child care make it difficult to justify spending 3-5 years in a position when they could be making more elsewhere. It also depends on what trainees want to do upon completion of a postdoc. Academic faculty positions are harder to come by, even in a strictly teaching capacity.

Existing NIH policies, programs, or resources

Expand the IRACDA program to be more than 20 universities. There should be more resources and funding available for those who want to pursue a teaching directed career.

Proven or promising external resources or approaches

No response

Response 2007

Perspectives on the postdoc roles and responsibilities

The postdoc is a valuable training exercise to learn more about what it is like to be an independent investigator than is feasible as a graduate student. Additionally, the added expertise from an additional, and hopefully different and complementary training experience helps to ensure that postdocs who go on to work independently in the scientific community will bring invaluable novel insights with them.

Fundamental issues and challenges

Postdocs are getting longer and longer and it is not a viable career path to simply stay in a training position into your mid to late 30's. There needs to be more opportunities at junior or training PIs promoted by the NIH for this system to sustain itself.

Existing NIH policies, programs, or resources

Please please please peg your minimum NRSA stipends to cost of living. These vary so wildly from place to place. It makes absolutely no sense to afford the same amount of personnel expenses on a grant for trainees living and working in Cambridge, MA the same as West Lafayette, IN.

Proven or promising external resources or approaches

No response

Response 2008

Perspectives on the postdoc roles and responsibilities

It's an opportunity to showcase your phd training the same time, produce preliminary data and apply for grants to establish yourself as an independent researcher.

Fundamental issues and challenges

It all boils down to staggering low salary and astounding working hours. Science is never a 9-5 job especially for those in their early career. Most post docs are in their late 20s or in 30s and are experiencing important life events like marriage, babies, first house etc. The salary and working hours forced by academic setting depressed overall quality of life, therefore it's inhibiting recruitment or hindering retention.

Existing NIH policies, programs, or resources

Higher salary scale! More budgets towards supporting pre and postdocs.

Regulated time commitment policies for postdocs via university, or PIs/ universities should be punished.

Proven or promising external resources or approaches

1. Higher pay
2. Regulated work hours
3. Trainings on funding opportunities
4. More early career awards with better pay

Response 2009

Perspectives on the postdoc roles and responsibilities

To me, the academic postdoc is meant for you to design and develop your own independent research project in order to take it with you to a full-time professor/PI or permanent research scientist position. I do think that a temporary postdoctoral position could also be taken in order to extend the time it takes to find a full-time position elsewhere after graduate school.

Fundamental issues and challenges

1. The postdoc pay is abysmally low, even compared to starting salaries of entry-level jobs. It's hard to justify taking that kind of pay when postdocs quite obviously have an advanced degree completed and 4-8 years of experience. The average American with a Bachelor's makes >80k a year with benefits (healthcare, 401k, etc.), and often postdoc positions are offering half that amount, sometimes without benefits. It's not an appealing position if the best offer is struggling financially for what will inevitably be an undetermined number of years.
2. I view the postdoc as the next step to move up into academia. Current postdocs are struggling to find and get offered an academic PI position, especially in a place that is safe for scientists from marginalized groups. It does not make the postdoc job market attractive if the career move afterwards may not be possible.
3. There is a big focus on doing postdocs apart from the university in which you did your graduate work. Graduate students often have started families, have life responsibilities, and ties to the area that make it not appealing to pick everything up and move for a postdoctoral position (especially when the pay is so low).

Existing NIH policies, programs, or resources

Fund more and more often. Strict requirements on NIH postdoc grants are often eliminating any chance for non-traditional postdocs to have their own funding.

Proven or promising external resources or approaches

No response

Response 2010

Perspectives on the postdoc roles and responsibilities

The best academic postdocs are highly skilled, highly experienced, and strongly motivated scientists. They drive some of the most ground-breaking new experiments. They are a crucial part of the workforce of academic science.

Fundamental issues and challenges

The likelihood for a postdoc in academia to obtain a tenure-track faculty position in academia is extremely low, unless they have worked in one of very few "elite" labs at very few "elite" institutions. Postdoc salaries in academia are also very low relative to positions in the private sector. And there are also very few long-term research scientist positions in academia that can truly offer enough financial stability to support a family. Given these three realities, recent PhDs are justifiably wondering, why bother with an academic postdoc? Why not just move to the private sector immediately after earning a PhD and get started on my long-term career? The academic postdoc track is seen as a dead-end, or perhaps a way-station that only delays what often seems like an inevitable transition out of academia.

Existing NIH policies, programs, or resources

Perhaps the NIH could actively support senior research scientists who've been productive and scientifically successful, but have not secured tenure-track faculty positions and therefore remain as skilled senior members of a lab. Perhaps such senior research scientists could be allowed to independently apply for major grants, without the assumption that whatever they do is subservient to their "PI". Perhaps NIH could increase their salary guidelines for postdocs, and also provide salary guidelines for senior research scientists. Perhaps the NIH could advocate for increased funding to support these highly skilled and vital members of the US scientific workforce.

Proven or promising external resources or approaches

No response

Response 2011

Perspectives on the postdoc roles and responsibilities

Postdoc is additional research training after a doctorate for pursuing an independent investigators pathway (typically, non-tenure track or tenure-track faculty) or research scientist pathway (typically, staff position at a research institute)

Fundamental issues and challenges

Challenges:

1. limited funding for international scholars,
2. faculty mentors not trained in postdoc mentorship and equity, justice and inclusion, and
3. postdocs are paid less and told to do everything from lab cleanup to grant ideation and writing. In general, when academic institutions are looking at adjuncts and non-tenure track faculty to carry out the day-to-day operations of a department, postdocs are considered even lower in the hierarchy and told to do departmental activities without any related pay.

This could include touring people who visit the lab, making souvenirs for guests visiting the department or teaching for free. International scholars usually look at the foundation, K99/R00, or R-level funding and cannot apply for other training grants like citizens do. This impacts retention. Less pay impacts recruitment. Faculty are typically European American and will not treat international scholars or scholars of color with the respect they deserve. Majority of the faculty will treat the postdoc as an extended PhD student or a pre non-tenure track. They will be told to write grants based on their ideas and then the faculty will put their name as PI; this is quite common. The culture and dynamics of the workplace and the way postdocs get treated impact the esteem, confidence and quality of life of the scholar. Interdisciplinary scholars will have an additional tough time as a postdoc as funding and mentorship is scarce.

Existing NIH policies, programs, or resources

This is the first time I am looking at these policies and programs when giving input to NIH. It would be nice that institutes that hire a postdoc recommend (a new) NIH training where postdocs are familiarized with postdoc mission, training outcomes and outputs, resources, challenges and unspoken truths. Tell postdocs that they don't have to do it because people up the chain are telling them to. Establish standards for postdoc training. For instance, there is a Ph.D./faculty handbook but rarely would one see a postdoc handbook at an institute. It is common for postdocs to get abused in the lab. International scholars cannot report abuse because they will have to go home if they do.

Proven or promising external resources or approaches

Share with postdocs that there is life outside of academia. It is unnecessary to seek validation by publishing or getting a tenure-track position. Go to the industry if you like.

Response 2012

Perspectives on the postdoc roles and responsibilities

It is a way to temporarily fund a full-time researcher—i.e. FT work for the length of a grant.

Because positions are soon after PhD, training and mentoring for the postdoc are expected. Postdocs stay up on literature for writing papers and often also oversee a project in terms of personnel (graduate students) and project management.

Fundamental issues and challenges

The number of postdocs has long outnumbered the number of academic positions available. It used to be that you didn't need a postdoc after a phd unless you wanted to go to an R1. Then you needed at least 1. Now i know postdocs that have 3-4 postdoc positions before either landing something or quitting Academia. Moving every few years, trying to publish a bunch, sometimes doing your own work in the margins after the grant you are paid from. At a pay rate that is significantly less than a faculty or industry position. It is not amenable to support a family to move every 2-3 years nor can partners sustain that.

Existing NIH policies, programs, or resources

I think less reliance on postdocs and more on MA, PhD, grant managers, and full-time permanent positions. That is hard to ensure, but I think it would be really cool to incentivize institutions to pool resources to recruit full time researchers, then have grants buy their time. I don't think more postdocs solves the problem. I think our over-reliance on them is the issue, and the idea that we need 9 years of postdocs. If we dont have enough FT research positions or faculty positions, then what are we training them for? Are grant investigators being held to their mentoring plans, is anyone checking placement after the postdoc, etc.

Proven or promising external resources or approaches

No response

Response 2013

Perspectives on the postdoc roles and responsibilities

I view the postdoctoral position as un-unionized exploitation of immigrant scientists. The pay is well below middle class standard of living in the urban areas that post docs live. Everyone know that no post doc or graduate student works less than 50hrs a week. It is just a scheme designed to poach international talent while they apply to get a green card so industry can accept them. In my cohort of 12 people no one is seriously considering post doctorate work. Everyone has to go to the industry as it is unlivable the wages.

Fundamental issues and challenges

Pay, and hours. The expectation of a post doc is to work 50+ hours a week for less than middle class wages. It's stressful, and employment is not guaranteed. Furthermore, there are very few principal investigator positions, so it is highly likely that you will have wasted your years trying to become a P.I. Finally, everyone has student loans, and to be 26 and not have any retirement savings, or money to purchase a home and then trying to balance the poor pay of post docs, its only people who have no other choice and are trying to come to America.

Existing NIH policies, programs, or resources

Unionize post docs, ensure employment, pay fair wages.

Proven or promising external resources or approaches

Get an arbitrator for when the post docs unionize.

Response 2014

Perspectives on the postdoc roles and responsibilities

Fundamental issues and challenges

Two challenges:

1. Future career opportunities
2. Lack of sufficient pay

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

Training beyond lab—finding job outside of academia

Response 2015

Perspectives on the postdoc roles and responsibilities

conduct research, collect data, publish papers, write grants. Engage in training for future career including academic positions and industry positions.

Fundamental issues and challenges

The current salary for postdocs is incredible low resulting in many grad students leaving for higher paying jobs and post docs leaving academia early for higher paying industry positions. Many graduate programs have already recognized this problem and have increased the graduate stipend, however the post doc stipend in many institutions, including my own, have not yet matched this increase in pay.

Existing NIH policies, programs, or resources

Currently the F32 funding program is only appealing for building resumes, but financially can be detrimental to post docs since most academic institutions no longer view post doctoral fellows as employees and therefore eligible for health insurance. I am not sure how this program could be changed, but I would be much more inclined to submit an F32 grant if I knew I would not receive a lower paycheck.

Proven or promising external resources or approaches

The IDP system has been beneficial for my graduate and post doc training.

Response 2016

Perspectives on the postdoc roles and responsibilities

Pathway to generate experience scientist for the future.

Fundamental issues and challenges

Uncertainty: As a postdoc after having PhD degree, it is difficult to digest the uncertainty of postdoc career. Years of postdoctoral experience doesn’t ensure any promotion in career. The ideal goal of a postdoc can be getting an academic position in universities, which is very difficult to get. Other ideal condition can be getting any major grant like K99/R00. I am k99/R00 research fellow. In the second year of K99 phase mostly I was looking for an academic position for the R00 phase. Applying and taking preparation for interview was killing most of my time. I didn’t get any advantage of having k99 in the position search. I got rejection from most of the universities before or after the preliminary interview. I can’t think how a candidate can get an interview call without having a grant! Anyone will easily understand how difficult it is to get a NIH funding but when I asked the interviewer about the tenure process, I got the reply that I will be judge same way as other faculty who joined without any grant. Although I waste a lot of my time as a postdoc to get the grant, I will not get any special consideration at the evaluation for the tenure process. Postdocs who finished PhD at similar time like me and jointed as a faculty immediately after PhD without prolonging the postdoctoral period for getting the grant are now in the process of getting Associate professor position while I am still trying to get an Assistant professor position. And if I get a position as assistant professor, I must go through the normal process of evaluation. This gives me the impression that I did a mistake by doing this long postdoctoral training which is not helping in any way to advance my career.

Existing NIH policies, programs, or resources

Other fundamental issue is financial discrimination:

In a very simple word, it is impossible to survive with a postdoctoral salary in most of the cities in USA. It is very strange that NIH has the same salary range for the postdocs throughout the country while salary in companies varies a lot based on the location of the company. There is no reason for a person to remain as

a postdoc while with the same experience that person can get a job in a company with three times more salary than the postdoc position. Earning less has a significant influence on the postdoc's life. For an example, personally, I was looking for a one room apartment in many housings complexes, but I didn't get any apartment as the rule in most of the apartment complexes in Massachusetts is that the salary needs to be three times than the rent of the apartment, which none of the postdoc earn according to the NIH salary range. Some apartment complexes suggested me to buy an insurance to get the assurance that I will be able to pay the rent on time. Consider a postdoc is so passionate about science and taking all the hurdle to apply for a very competitive grant (like k99/R00) and got the grant, that will not have any influence on his/her salary. The postdoc who did not get the grant, quit science and join the companies earn three times more than the postdoc who got the grant. Most of the postdocs are in their early family life, so in this stage financial condition has a huge role in their person life. Although they wanted to be in academic, due to less salary they need to move out of academic to support their families.

Proven or promising external resources or approaches

Recommendation related to uncertainty in the career:

There should be a year limit how long a person can remain as a postdoc. After that period the institutes must promote them to the new phase, if possible, to an independent role. Postdoc who will come through a major funding mechanism should get privilege for getting an academic position. If a postdoc spend a significant amount of time to obtain a grant during the postdoctoral period and prove the successful track record, they should evaluate differently during the process of tenure process to encourage their achievement. Without these changes there is no meaning to remain as a postdoc or trying to get a grant in the postdoctoral period to get independence as getting grant can easily cost two to three years of the postdoctoral time.

Recommendation related to salary:

NIH should have a salary recommendation based on the location of the postdoc. The salary if not same, should be similar as the salary of the same postdoc in the industry of that area. K99 or similar funding mechanism salary should be heavily adjusted to encourage postdocs to choose this path of independence. Without these changes it will be difficult to bring or keep brilliant postdocs in science. Now the postdoc we are seeing in academia, are mostly J1 visa holder who have no option to move to the company. So, the actual motivated scientists are reducing every day. As soon as they get the green card or work permit, they are moving to the industry. But many of the postdoc started their career as a postdoc to build an academic career and live a decent life.

Response 2017

Perspectives on the postdoc roles and responsibilities

Initially, postdoctoral training meant an opportunity to broaden my interests and get training in a new area. Now, it is basically a holding position until I get a faculty position or other job. I write grants. I plan and carry out experiments. I analyze data. I write papers. I train and supervise students. I functionally act as a direct supervisor for multiple students, but my institution doesn't recognize that. I can't be listed as their official supervisor or sign the paperwork they need to register for class or work. My PI is very willing to give me feedback on grants and my writing, but not everyone is so lucky. Postdoc sometimes feel like a position that was created just so highly educated people could be minimally paid for their labor. Faculty jobs are so impossible, if you want to do research, you get stuck as a postdoc. If you've been a postdoc "too long" people start looking down on you, including funders. If it's been more than 5 years since your PhD, you're no longer eligible for K99 onwards and many other funding sources. Industry doesn't care about postdoctoral training, and from what I've heard they consider it a waste of time. I enjoy my work, projects and colleagues, but the longer I am a postdoc, I feel more disrespected and undervalued. Ideally, grad school would teach you to be a scientist, a postdoc would teach you how to be a PI and run a lab. There's no training on how to be a PI unless your postdoc mentor specifically discusses those things with you.

Fundamental issues and challenges

The biggest issue is that postdocs are not paid a living wage. The pay scale is appalling considering the level of education. While it's a "training" position and some of the "compensation" is supposed to come from the education received, that is a joke. Postdocs mentor younger/less experienced lab members, plan

and execute experiments, write grants, write papers, analyze data. Postdocs are the ones doing the training. If you don't have a good mentor, the only "training" you will probably get is some seminars series. We all know that the majority of work shown in published articles was done by postdocs, grad students and staff. Academic science COULD NOT EXIST without postdoc labor. I have been a postdoc since 2017. I live in a HCOL city and qualify for low income housing. Luckily I am single, supporting a child or family on my pay would be impossible. If i had student debt, I couldn't manage on a postdoc salary. The only reason I have anything saved for retirement is due to laws in my state. Postdocs miss out on years critical for building retirement savings. The pay is also just insulting. It shows the absolute lack of respect academia and the rest of society has for postdoctoral and scientific work. Postdocs are not treated as valued, contributing members of the scientific workforce. Most of my grad school peers left academia following graduation due to the pay. Due to the current economic/political climate the generation currently entering grad school won't put up with not being adequately paid. The current postdoc system is simply not sustainable. Being a postdoc means choosing intellectual fulfillment over financial security. It shouldn't mean that.

Existing NIH policies, programs, or resources

The time since PhD limit on K99 and K01 awards needs to be abolished. As many funding sources follow the NIH guidelines, this means I'm "too old" for many funding sources. If I can't get funding, I won't get a faculty job, and I'll just become an older postdoc. The limit traps people in training positions. Why does years since PhD matter? I know there are exceptions for parental leave, sick leave, and changing fields. The "changing fields" exception is so subjective. These limits also don't consider that having a postdoc with a bad or unfit mentor can run out this clock and leave the postdoc with limited options. I was stuck in a bad mentoring situation just prior and during COVID and wasted three years with no papers to show for it. Everyone in academia KNOWS that there are toxic, bad mentors, but there's no formal acknowledgement. Why make exceptions? Just do away with the years from PhD limit.

Proven or promising external resources or approaches

There needs to be training on how to be a mentor and manager. Everyone in academia has been directly impacted or knows someone who was directly impacted by a toxic or inept mentor situation. I think requiring PI's to receive training in mentoring would help. There needs to be specific training for postdocs in "soft skills"--managing, mentoring, budgeting. Running a lab is like running a small business, and most postdocs have no business experience. There aren't enough faculty jobs for every postdoc, so there needs to be acknowledgment of a senior/staff scientist path and training.

Hostile work environments need to be taken SERIOUSLY. It often feels like PI's can get away with anything. If it is racial discrimination or sexual harassment, it might be taken seriously by your institute, but general maltreatment is totally ignored. I worked in a lab where there was no sexual or racist harassment, but it was incredibly toxic. The PI belittled lab members in front of the group. Implied that I should not have passed my PhD qualifying exams. Lab members would not take time to help one another because they were so afraid of not completing their own work. I was more nervous before one-on-one meetings with this PI than I was before presenting in front of a 1,000 person audience at an international conference. Nothing was done and there was nothing that could be done. The students had some resources, but there were none for postdocs. A postdoc ombudsman or postdoc support services would be helpful. The culture also needs to change that that type of behavior is unacceptable.

Response 2018

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

Feeling of disengagement from society and its problems while establishing careers or furthering the careers of their sponsors.

Fear that public support for science is eroding, making careers less attractive and tenable.

Existing NIH policies, programs, or resources

Provide postdoctoral training in science communication, conveying the results and excitement of basic and applied science to the general public, including science in other disciplines.

Provide postdoctoral training in risk communication, identifying and conveying the scientific results that are relevant to audience members decisions.

Science communication focuses on scientists' need to be heard.

Risk communication focuses on audience members' need to make decisions, where science might the helpful

Response 2019

Perspectives on the postdoc roles and responsibilities

A postdoc position is meant to serve as a stepping stone from graduate school to full employment, especially in for those who hope to establish an independent laboratory. A postdoc made sense for me as I wanted some time to prepare for the transition from trainee to independent investigator. I wanted to learn more about how different labs operate, and, most importantly, I wanted to be able to think seriously about what direction I wanted to take in my future independent research. I assumed that, in return for these benefits, I would serve as a senior member of my mentor's laboratory who may bring in new skills and could be trusted to manage/develop projects at an advanced level. My experience as a postdoc has shown me that these goals are only secondary to the real purpose of the position—which is to publish at all costs. The postdoc is there to publish so they can be competitive for a job. The mentor hired the postdoc to help them publish. There is no time for growth.

Fundamental issues and challenges

I cannot state strongly enough how disappointing and heartbreaking my experience with academic science has been. I've always felt confident in my ability to contribute productively to the scientific community. What's been so unbelievably frustrating is that my faithfulness to my values as a scientist is what made my continuation in this role unbearable. The pervasive entrenchment of these issues at every level of the scientific process is disturbing, frankly. Upon starting grad school, I was told that my job was to be the best scientist that I can—to be rigorous, curious, transparent, etc. I happily accepted this expectation, as it was what I already expected from myself. But this was a lie. For most people, it is impossible to be a good scientist.

Obviously there are many passionate scientists who aim to perform their duties responsibly, but it seems like everything is set up to make that as difficult as possible. We must publish often, and in "high-impact" journals, whose designer brand images stand to benefit from our bitter infighting for the honor of appearing in their pages. The rush to collect data precludes engagement in activities essential to performing effective science—no time to ponder theory or review statistics or update protocols. We must publish so we can get grant money. Then, our grant money is burned on insultingly overpriced essential supplies from monopolized research supply providers. Our work is messy, and we're lying to ourselves if we say it isn't. We are oversaturated with low-quality publications. We have no money leftover to pay trainees. We are exhausted and demoralized. Innovation is stifled, and progress only happens despite these conditions, not because of them. The general public is losing trust in us due to the proliferation of predatory journals, which thrive off of publish-or-perish culture.

Existing NIH policies, programs, or resources

Re-evaluate our relationship with publishing. De-monopolize research supply providers. Trainees won't truly be respected until this happens.

Proven or promising external resources or approaches

Re-evaluate our relationship with publishing. De-monopolize research supply providers. Listen to trainees. Show some respect for the values of science and for the money given to us by the general public to perform this research.

Response 2020

Perspectives on the postdoc roles and responsibilities

Training period that facilitates your transition from a mentored researcher to a fully independent researcher. Roles/responsibilities include writing research grants, mentoring students, designing and conducting experiments, presenting research results, collaborating with other research labs or lab members, publishing original research articles, and peer review of research manuscripts.

Fundamental issues and challenges

1. Salary is completely unrealistic; especially for people living in larger cities. I should not have to rely on support from a union for a fair wage. As a government institution, which provided salary increases to its' employees to account for inflation, it is unconscionable to not do the same for postdoc salaries.
2. Work-life balance does not allow for raising a family with any thoughtfulness or care towards other human beings. Research experiments often require being in the lab 7 days a week, but we can't afford to live close enough to the lab to achieve this without working extremely long hours. Raising the salary would help alleviate this problem.
3. Expectations for timelines have become unrealistic.it is not funny to suggest that you do a second PhD as a postdoc.this favors the PI's interests and not the trainee. The NIH needs to take the initiative to help mediate this problem.for example, ask PIs to justify why postdocs stayed longer than 3 years. Labs with postdocs who routinely stay above 5 years is an red flag.
4. No retirement benefits provided.
5. NIH-funded postdocs are still asked to work on other projects not related to their proposal. This creates an unrealistic expectation of running many projects, despite having your own NIH funding, which leads to a very unpleasant work-life balance and an extended postdoc timeline. NIH needs to make it clear that there are penalties for PI's who try to coerce postdocs into running additional projects beyond their funded proposal.
6. NIH needs to reform the peer review process for postdoc grants. Applications should not be rejected by reviewers who cannot objectively critique the scientific foundation of a proposal. Bad reviews, even if unjustified from a scientific perspective, are all it takes to push talented scientists away from postdoc.

Existing NIH policies, programs, or resources

1. Limit the length of a postdoc to 3 years. Anything longer should require a special exemption signed by both the postdoc and the mentor.
2. Increase the salary to an acceptable living wage based on the location of the postdoc.it does not make sense to pay all postdocs the same salary regardless of location.
3. Set clear guidelines for the time commitment required for NIH F32 and k99 fellowships. It should be clear to PI's that they cannot coerce funded postdocs into working on other grants for them.
4. Improve child care benefits and retirement benefits to match NIH employees

Proven or promising external resources or approaches

No response

Response 2021

Perspectives on the postdoc roles and responsibilities

The postdoc is a training period between PhD and next step (either academic or non-academic scientist). The roles are designing research directions, performing experiments, mentoring students, writing research grants, writing and publishing original research, presenting results, and peer-reviewing papers.

Fundamental issues and challenges

The salary does not pay a living wage, especially for postdocs living in larger cities. I should not be living paycheck to paycheck as a Ph.D. level scientist. The fact that the NIH has not adjusted salaries to account for the inflation is insulting. The current situation is one in which people are trapped in a system in which

they are used and taken advantage of as cheap labor. Additionally, the lack of retirement benefits and limited health benefits further underscore the little value placed on scientists who are performing the bulk of the research work. In addition, the unrealistic expectations with regard to work/life balance and the low pay make it impossible to start a family in good conscience. This forces people to choose between staying as postdocs to further their potential academic career and having a family. Furthermore, the current expectation of people doing a postdoc that is as long as a PhD is unacceptable. This only benefits the PI, is detrimental to the career of the postdoc, and further exacerbates the problems of work/life balance. Another problem is that postdocs who have secured independent funding are still asked and expected to work on projects that the PI has grants for. This dilutes the postdoc's time and makes it harder for them to focus on the research that they are funded for, serving to extend the postdoc timeline. Finally, it can often feel that a postdoc is just a glorified graduate student. As a next stage in career development, there should be a more clear delineation between the roles and responsibilities of a graduate student and those of a postdoc (ie, more leadership and mentoring, less bench work science).

Existing NIH policies, programs, or resources

The upper length of a postdoc should be limited to four years. Anything longer should require a special exemption with rigorous assessment (not just a form that is routinely signed). The salary should be increased to be an acceptable living wage based on the location of the postdoc, as it does not make sense to pay all postdocs the same (ie, cost of living in a big city is much higher than in a rural setting). Significant childcare benefits and retirement benefits should be included. As a government institution, the NIH should give postdocs the same benefits it affords other government employees (ie, like the employees who do research at the NIH).

Proven or promising external resources or approaches

No response

Response 2022

Perspectives on the postdoc roles and responsibilities

The postdoctoral period provides individuals with additional research training and exposure. I view this as an opportunity to expand upon specific skills required to efficiently and successfully establish an individual program of research.

Fundamental issues and challenges

1. Postdoctoral positions in clinical disciplines (e.g. medicine and nursing) are difficult to identify. Ideally there would be a system for central posting. I'm completing my PhD in nursing and am interested in a postdoctoral position, but have not been able to locate one either in the academic setting or NIH.
2. Postdoctoral positions in clinical disciplines (e.g. medicine and nursing) do not offer a livable salary for individuals in these field who often pursue doctoral training later in life. Spending 18 years in clinical practice caring for critically ill children prior to pursing my PhD has been invaluable to me and will continue to inform my research, however I am unable to take a $100k paycut mid-career given that I have a family now.

Existing NIH policies, programs, or resources

Create postdoctoral positions in clinical disciplines that allow for continued clinical practice. This would allow researchers to maintain the clinical relevancy necessary for meaningful research as well as to both augment their incomes to make postdoctoral training economically feasible.

Expand postdoctoral positions for clinical disciplines and translational science.

Proven or promising external resources or approaches

Create centralized posting system for available positions which is searchable by specialty/topic/discipline. Allow candidates to post CVs so researchers who can accommodate postdoctoral positions could reach out to interested candidates. One of the barriers to diversity in research is the current system of having PIs write in support for candidates they know rather than creating positions which could be applied and interviewed for. The current system is more about who you know than your qualifications.

Response 2023

Perspectives on the postdoc roles and responsibilities

Garner skills in order to successfully start up an academic laboratory with research topics and skills learned throughout postdoc. One should be be equipped with the skills of writing grants, manuscripts, managing and mentoring employees, and the financial aspects of starting up and running a lab.

Fundamental issues and challenges

Post docs are now a second PhD, you do not gain the skills to run a lab, only the skills to perform research at a somewhat higher level. With PhD projects become longer and more difficult, a postdoc has diminishing returns in terms of the scientific techniques to learn. The other parts of being an academic researcher are not taught during the postdoc either so there is no point. The postdoc exists for cheap labor for academic institutions with the false promise of starting an independent research group.

The salary is not livable and needs to be around $80K, especially in high cost of living areas. The PhD is clearly not values by academic institutions, so people are going elsewhere, i.e. where they have the means to start their lives as they have been delayed due to graduate school.

Existing NIH policies, programs, or resources

Higher salary. Less scientific training, more training of how to run a lab.

Proven or promising external resources or approaches

Higher salary.

Response 2024

Perspectives on the postdoc roles and responsibilities

Postdoctoral positions are typically temporary research positions for individuals who have recently completed their doctoral degrees. The role of a postdoctoral fellow is to conduct research under the supervision of a principal investigator or mentor, gain additional experience in their field, and prepare to transition to an independent research career. The responsibilities of a postdoc may include designing experiments, conducting research, analyzing data, presenting research findings at scientific meetings, writing research papers, and applying for funding. Postdoctoral positions are an important step in the career pathway for many biomedical scientists, and can provide opportunities for career development and networking.

Fundamental issues and challenges

There are several Fundamental issues and challenges that may inhibit recruitment, retention, and the overall quality of life for postdoctoral trainees in academic research. Some of these challenges may include:

Limited career prospects: Postdoctoral trainees may face limited career prospects after completing their postdoctoral training, which can be a major source of stress and uncertainty.

Financial insecurity: Many postdoctoral positions offer relatively low pay and lack benefits such as health insurance, retirement plans, and paid time off, which can lead to financial insecurity and instability.

Work-life balance: Postdoctoral trainees may struggle to maintain a healthy work-life balance, as they may be expected to work long hours and weekends to meet research deadlines.

Lack of mentorship and career development opportunities: Many postdoctoral trainees may lack access to mentorship and career development opportunities, which can limit their ability to develop the skills and knowledge necessary to pursue independent research careers.

Addressing these issues will require a multi-faceted approach, including increased funding and support for postdoctoral trainees, improved mentorship and career development opportunities, and a commitment to promoting diversity and inclusion in the academic research community.

Existing NIH policies, programs, or resources

There are several existing NIH policies, programs, or resourcesthat could be modified, expanded, or improved to enhance the postdoctoral training ecosystem and academic research career pathways. Some of these include:

Increasing the number of postdoctoral positions: The NIH could provide additional funding to support more postdoctoral positions, allowing for a greater number of trainees to gain valuable research experience.

Improving compensation and benefits: The NIH could encourage or require institutions to provide better compensation and benefits for postdoctoral trainees, including health insurance, retirement plans, and paid time off.

Promoting mentorship and career development opportunities: The NIH could provide additional funding or require institutions to develop and implement formal mentorship and career development programs for postdoctoral trainees.

Supporting diversity and inclusion initiatives: The NIH could establish or expand programs aimed at promoting diversity and inclusion in the postdoctoral community, including recruitment of trainees from underrepresented backgrounds.

Facilitating transition to independent research careers: The NIH could provide additional funding and resources to support the transition of postdoctoral trainees to independent research careers, including grants and fellowships designed to support early-stage investigators.

Overall, improving the postdoctoral training ecosystem and academic research career pathways will require a concerted effort from multiple stakeholders, including the NIH, academic institutions, and the research community at large. By working together to identify and address these challenges, we can help ensure a bright future for the next generation of biomedical researchers.

Proven or promising external resources or approaches

There are several external resources and approaches that could inform NIH’s efforts to enhance the postdoctoral training ecosystem. Some of these include:

Mentoring networks: Developing and supporting mentoring networks that connect postdoctoral trainees with established researchers and professionals in their field could improve training and career development opportunities.

Professional development programs: Creating and supporting professional development programs that provide postdoctoral trainees with the skills necessary to succeed in academic research and other career pathways.

Career services: Providing career services to postdoctoral trainees, including job search assistance, interview preparation, and resume building, could help them transition to successful careers after their postdoc.

Diversity, equity, and inclusion (DEI) initiatives: Increasing diversity, equity, and inclusion within the postdoctoral training ecosystem could improve the overall quality of life and career opportunities for all postdoctoral trainees.

Collaboration and networking opportunities: Encouraging collaboration and networking opportunities between postdoctoral trainees, researchers, and professionals in academia and industry could facilitate the transfer of knowledge and improve career development opportunities.

Transparent and equitable policies: Implementing transparent and equitable policies that address issues such as compensation, benefits, and work-life balance could improve the overall quality of life and job satisfaction of postdoctoral trainees.

These are just a few examples of external resources and approaches that could inform NIH’s efforts to enhance the postdoctoral training ecosystem.

Response 2025

Perspectives on the postdoc roles and responsibilities

The postdoc and the PI should ultimately have a symbiotic relationship. The postdoc should certainly be a reliable colleague for the PI through providing technical expertise, writing and editing manuscripts, and performing other duties as appropriate; however, the PI should provide ample opportunities for growth for the postdoc. These opportunities should include learning new laboratory techniques, access to career development opportunities (i.e., seminars, workshops, courses, networking), opportunities to increase the quality and quantity of publications, and outstanding mentorship.

Fundamental issues and challenges

Challenges to recruitment, retention, and quality of life for trainees include burnout following completion of the doctorate, compensation (especially compared to opportunities in industry jobs), benefits (paid time off, maternal leave, etc.), and the overall culture in academia. Culture in the academic work place is overly political with very complex personalities, which can be toxic at times.

Existing NIH policies, programs, or resources

I'm not quite sure how to answer this question, as I'm not entirely familiar with NIH **policies, programs, or resources**. Perhaps these NIH entities could be accessible and easily digestible for the trainee.

Proven or promising external resources or approaches

I'd consider looking at various industry leaders that have the best rates of recruitment and retention.

Response 2026

Perspectives on the postdoc roles and responsibilities

A postdoc position provides training for becoming an academic PI. However, most postdocs cannot become PIs based on numbers alone (i.e. the number of postdocs exceeds the number of open faculty positions). Practically speaking, most postdocs are heading toward a position other than academic PI.

For postdocs who do plan to become PIs, the training they receive varies widely. Some postdocs supervise junior lab members and therefore have management experience in preparation for running their own lab, while other postdocs have no supervision responsibility. Similarly, some postdocs teach classes or complete formal teaching training, while others are actively discouraged from teaching, even if teaching will be central to their future career. Grant-writing experience also varies widely depending on the expectations of each advisor. The central focus of a postdoc is generating publishable data, and some postdocs have little time to learn the other tasks they will do as a PI.

For the postdoc position to make sense as a traineeship for a future PI position, postdocs would need to have a reasonable expectation that they can become a PI, and they would need to have mentored experience in the tasks they will do as a PI (including lab supervision, teaching, and grant-writing). The term "trainee" is not accurate if most postdocs will never become PIs and are not necessarily receiving much mentored training in the various roles of a PI. As a postdoc, it is easy to feel that the term "trainee" is simply a justification for low pay. In industry, people with PhDs who conduct research are called scientists, not trainees, even when they have exactly the same qualifications and experience as postdocs. When I look at my peers in industry, including my classmates from grad school, I feel exploited and disillusioned with my choice to stay in academia.

Fundamental issues and challenges

I am a postdoc in the Boston area, and I am also a parent. It is difficult for me to support one infant on a postdoc salary. The monthly cost of the daycare provided by my university is $2,972/month, more than half of a postdoc's gross pay. We searched extensively, beginning 7 months before our baby's birth, and secured a spot in another daycare for $2,000/month, which is the lowest we can reasonably expect to pay for a licensed daycare center in the Boston area. As it is, my partner and I can barely make ends meet, and if we had a second child, our financial situation would become untenable. It is difficult to stay through the end of my postdoc knowing that I could earn dramatically more in industry, and there is no guarantee that I will eventually become a PI in exchange for these low-paid years as a postdoc.

Postdoc salaries should be adjusted for cost of living in the location the postdoc is working. Although some postdocs can choose to live in places with lower cost of living to make the postdoc salary more livable, others are more constrained in their choice of location. I am a transgender person in an interracial relationship parenting a biracial child, and my family cannot safely live in many parts of the country that have dramatically lower cost of living. For us, living in a liberal city is a matter of personal safety and, increasingly, basic rights to healthcare access.

The duration of postdoc training can worsen financial stress, particularly when escalating expectations of top-tier journals lengthen the publication process. Papers in top-tier journals now include many more figures than they did in the past, and these escalating expectations can lengthen the duration of a postdoc, intensifying financial stress.

Existing NIH policies, programs, or resources

Currently, postdoc salaries are set nationally, without adjustment for cost of living. This makes recruitment and retention challenging for PIs in areas with high cost of living, and creates a financially untenable situation for postdocs with families in high-cost locations. Postdoc salaries should be adjusted for cost of living in the location where the postdoc is working.

Proven or promising external resources or approaches

No response

Response 2027

Perspectives on the postdoc roles and responsibilities

I was a postdoc for 2 years following my PhD before accepting an industry position. I view postdocs as professionals in their own right, not simply as trainees.

Fundamental issues and challenges

The single greatest issue with Postdoctoral training is compensation. It is literally a joke—a punchline—for anyone who has gone through academic training. Nothing else—programming, retreats, resources, etc. would come close to the quality of life improvement that a substantial increase in compensation would provide.

Existing NIH policies, programs, or resources

Increase compensation. I recruit PhDs for my current company, and if I’m competing against an academic postdoc, I win. It’s not even close. Even as a CRO, which doesn’t pay nearly as well as, say a large pharma company, we can beat the typical postdoc salary by about $10-20k.

Proven or promising external resources or approaches

For the love of God, increase postdoc compensation.

Response 2028

Perspectives on the postdoc roles and responsibilities

A professional, postgraduate researcher in the lab of a principal investigator. A postdoc is a dedicated researcher that assumes a leadership role on their project and in the lab more broadly. They significantly contribute to the training of graduate students, especially in experimental operation, since most PIs are stretched thin and don’t do much experimental work on their own.

The postdoc continues to develop the skills of designing and implementing research projects, but brings with them an entire PhD’s worth of training and skills, often promoting consistent progress on their (and their mentees’) projects and the smooth operation of the lab.

For the postdoc, the experience in a new lab allows them to gain exposure to scientific questions and techniques beyond their PhD experience. For those postdocs interested in pursuing academic/basic science careers afterwards, a postdoctoral position can be a great place to practice proposing new projects and forming the foundation of their independent research program.

Fundamental issues and challenges

I have taken on a huge opportunity cost in terms of professional development and financial stability, because a postdoc is only necessary for applying for an academic position in my field. As number of positions remain small and the costs are high, it is no surprise to me that fewer young scientists are signing up to be postdocs, and a part of me feels gullible for accepting this deal.

I am payed significantly lower (approximately half) than my peers in the private sector, with the implicit expectation of working longer hours to ensure "meaningful progress" on my project. As well, while my peers in industry are able to actually save appropriately and afford to live in a region with in a robust science job market, I can only afford to save about 4% of my net income per month and have no contribution from my employer towards a retirement fund. I frequently rely on my partner's income to meet expenses such as car maintenance.

A Postdoctoral position is necessary for attaining an academic job, but unnecessary and sometimes detrimental to an applicant trying to change sectors, say into industry or the national lab system. Because of the small odds of landing an academic job and the limited demand for my particular technical skills in the private sector, I've experienced deep self-doubt and uncertainty throughout my three years as a postdoc.

Particularly since I started remote in 2020, my time as a postdoc has been isolating. Not only did it take more than a year to get to know my labmates, but there is much less interaction outside the lab since I don't have a cohort like in graduate school. As well, I commute 1 hr+ each day and leave between 5-6 to be home with my spouse, limiting after-hours interaction.

Existing NIH policies, programs, or resources

The NRSA zero-level postdoc salary of $56K is not reasonable for a PhD-educated professional researcher, and does not reflect the huge cost-of-living disparity across the country and recent high inflation rates. Stipends should be tied to regional median cost-of-living estimates, which is regularly measured by the Federal Reserve.

Proven or promising external resources or approaches

Along with compensation in-line with cost of living, support for staff scientist positions on extramural grants could alleviate the labor shortage. Not every postdoc is looking to establish an independent research career after only 3-4 years after their PhD, and would be fulfilled continuing to work in a professional role in a basic science setting under a PI. Viewing postdoctoral positions as training and temporary appointments limits this opportunity.

Response 2029

Perspectives on the postdoc roles and responsibilities

I view the academic postdoc as a training position where PhD scientists are transiently employed by a laboratory to gain additional experience in their intended field. Postdoc positions are for training purposes and thus the PI hiring a postdoc should keep this in mind. Postdocs are not "cheap technical help", but rather aspiring top level scientists who are employed for training purposes.

Fundamental issues and challenges

The main problems with PhD postdoc positions are the lack of appropriate benefits and pay for such a professional position. Earlier, when US PhD training took 4-5 years, a short postdoctoral position was suitable. However, with PhD training now spanning 7-8 years, it is difficult to convince PhD scientists to take a "double penalty" and spend another 7-8 years in a transitory position with low pay and a benefits package that often includes no retirement benefits. This is especially relevant when MD fellows get paid double or triple the salary of postdocs and then "moonlight" to make additional salary, often at the expense of their laboratory obligations. It is particularly ridiculous when the postdocs need to train the MD fellows because they lack laboratory skills, while getting paid a fraction of the salary. The laboratory expertise of postdocs should be appropriately valued, regardless of whether the postdoc has a PhD, MD, or both.

Existing NIH policies, programs, or resources

Improving the postdoctoral training system begins with doctoral studies. Relieving the undergraduate debt burden for doctoral students would be a good way to ensure that they don't begin with a "penalty" relative to foreign students who most often have no undergraduate debt. Streamlining the undergraduate with BS to PhD programs that enable students to enroll in a PhD program after two successful years of undergraduate study would enable students to save two years of tuition as beginning their PhD studies two years earlier. This would enable students to obtain their PhD degree by age ~24. They could then complete their 5 year postdoctoral studies before age 30. This is a huge issue, especially for students who plan on having families. PhD programs should be better defined and have milestones for success, with stipend increases for achieving candidacy and also increasing the stipend to postdoctoral level stipends after the 5th year. This will provide an incentive for PhD advisors to enable their PhD students to graduate in a timely fashion. Presently there is little incentive for PhD advisors to encourage a well trained senior PhD student to graduate. They would rather have them function as postdocs or technicians while continuing to pay them as a graduate student. Fixing these types of conflicts of interest would be immensely helpful for encouraging PhDs to pursue postdocs. Providing for lab manager funding for labs would also discourage using postdocs for this purpose. The postdoc position should have a 5 year limit. Beginning in year 3 of the postdoc, postdocs should be eligible for submitting R01 grants. This would remove another conflict of interest where the PI can prolong the postdoc training period by keeping the postdoc in a holding pattern while they continue to work under their paygrade.

Proven or promising external resources or approaches

No response

Response 2030

Perspectives on the postdoc roles and responsibilities

Postdocs and research scientist do everything: from teaching and mentoring students (undergraduate/graduate) to writing grant and manuscripts, to perform experiments, to attend conferences.

Fundamental issues and challenges

Not enough tenure track positions for postdocs to transition to and Not enough support to the research scientist track, which is a great opportunity for team scientists.

Financial remuneration is not reflective of the effort delivered.

In several academic institutions, postdocs do not qualify for retirement benefits.

Postdocs and research scientist are treated as cheap labor that promote the careers of their MD colleagues. There is not accountability for the PIs that exploit postdocs (especially, international postdocs)

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

Provide administrative supplement grants to postdocs

Increase salaries

Establish accountability checkpoints for the PIs. Enforce multi-mentorship to create a supportive, professional and non-professional, environment.

Support international students with immigration information.

Support the research track as alternative for postdocs to continue producing exciting science (salaries, special funding opportunities)

NIH should ask for feedback from the postdoc community in a regular basis (e.g., 2 or 3 years) to determine whether the programs in place are having the desired impact. In our fast changing society regular checkpoints will inform whether changes need to be done to obtain the desired effect. Preventive vs. correction action

Response 2031

Perspectives on the postdoc roles and responsibilities

I view the postdoctoral role as an opportunity to establish oneself as an independent researcher, continuing the PhD training into an individual line of scientific questions not directed by the PI, but aligned with the research in the lab where training occurs. In this position, the responsibilities and opportunities should be guided by what the postdoc is looking for in future career stages.

Fundamental issues and challenges

From a graduate student perspective, academic incentives revolve largely around number and impact of publications, and prestige of academic institutions where training occurs. Therefore, recent PhD graduates focus on maximizing these metrics and tend not to focus on the fit between their career aspirations and the environment created by the PI and lab they join. However, biotechnology and pharmaceutical hiring managers prefer candidates with industry experience rather than academic experience, making publications and institutions less important when postdocs leave academia. This inhibits recruitment because it makes postdoc training less valuable for PhD students intent on following industry careers.

Moreover, there is very little difference in stipend levels between academic institutions, but the pay gap between academia and biomedical industry for a recent PhD can be two to three times the starting postdoc salary, making the postdoc role objectively less attractive in short and long term monetary returns. This is very important for PhDs carrying student debt and international researcher looking to offset the costs of moving their lives (and at times families) to the US.

From a postdoc perspective, postdoctoral training is largely ruled by the will of the PI who funds the position, and the competitive nature of leading research groups push PIs to require postdocs to spend all their time furthering the research program funding the lab. Therefore, postdocs have little space to pursue training for industry positions, and at times even for faculty positions. In essence, postdocs need more control over their funding and time in order to better negotiate their positions, responsibilities, and expectations.

Existing NIH policies, programs, or resources

Evidently, shrinking the pay gap would be a major element. However, even at a lower salary, academic positions tend to offer more stability than job largely ruled by “at-will” contracts (the standard in biomedical industry). The stability can offset some of the pay differential. A postdoc position would be even more attractive if postdocs had more independence than graduate students with respect to their funds and training opportunities. For example, today, a postdoc can only pay for professional conferences and training using university resources if the PI requested such resources in a grant and if the same PI allows the postdoc to use it for such activities. If all postdoctoral positions funded by the NIH had a professional development yearly stipend, it could be used to pay for online training (such as Coursera or LinkedIn Learning subscriptions), in-person workshops, or travel-related costs for professional conferences (travel, lodging, fees).

By transferring control of these funds to the postdoctoral researchers themselves, the NIH would achieve better distribution of training funds to the entire postdoctoral workforce (not just those in top tier universities with large labs and even larger research grants), and a guarantee that all postdocs would have the opportunity to obtain professional training outside academia. This could be offset by prohibiting the use of grant moneys to fund postdoc professional training (only PIs and (under)graduate students could use the funds, for example).

Proven or promising external resources or approaches

Multiple institutions implement Individual Development Plan where postdoc and PI discuss and put on paper the plans, expectations, training, and other activities proposed for the following year. This helps both parts clarify expectations regarding the use of the postdoc’s time and the lab’s resources for the upcoming year, and what each part expects from the other.

Postdocs looking for faculty positions could ask to be more involved and trained in grant-planning and teaching activities, while postdocs looking for industry positions could be given the time for training of industry-related skills, while PIs can clarify their expectations regarding lab management and student supervision.

For example: https://www.med.upenn.edu/postdoc/postdoc-training-individualdevelopmentplan.html

Response 2032

Perspectives on the postdoc roles and responsibilities

1. Design projects/experiments, perform experiments, analyze/organize data, write/publish manuscripte.
2. Felowship/grant writeing.
3. Collaborate with lab members/others, provide feedback (suggestion/advice if possible) to others work.
4. Metoring some students.
5. Review manuscripts.

Fundamental issues and challenges

1. Relatively low salary compared to the living cost (especially for house/apartment renting) in big cities.
2. Maybe it is helpful for postdoctor candidates to choose the right lab for them if there is a public evaluation report about the PI and lab.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

1. If there are public available vedio protocols (from well established labs) for experiments/data analysis, that will be helpful.
2. More zoom classes about project desigining, experimental performing, data analyzing, manuscript writing, and fellowship application.
3. Increase salary to against the inflation.

Response 2033

Perspectives on the postdoc roles and responsibilities

To me, a postdoctoral position serves as a stepping stone to get the skills and training necessary for a faculty position. It also serves as a time for the post doc to figure out if working at a university is their main career goal or if they wish to pivot to a different career goal.

Fundamental issues and challenges

Right now, post docs are underpaid and that's the number one reason why graduating graduate students are taking positions in industry, pharma, etc. In addition, there are not a lot of protections for post docs. Often, post docs can be easily overworked and taken advantage of (especially international post docs). In addition, institutions don't often provide resources for things such as child care which is a barrier for women who wish to do a post doc. It's hard to justify moving to a new state or city when the pay isn't the best and when there aren't good resources to ensure your family is taken care of in this new location.

Existing NIH policies, programs, or resources

I believe that the funding resources (T32, F32, F99/K00, K99/R00, etc.) are good resources and allow the post doc to build a competitive CV for faculty positions. I think that post docs need more education on the F32 payback policy. Not many post docs realize that this policy exists and some post docs feel trapped once they discover they don't have the flexibility to change careers easily. I enjoy when IC's host webinars on funding resources/professional development. I've attended a few of these, which have been very informative in learning how to be competitive for funding and what funding/policies exist.

Proven or promising external resources or approaches

I don't know of any resources off the top of my head.

Response 2034

Perspectives on the postdoc roles and responsibilities

As a fifth year grad student, I am currently interviewing for academic postdoc positions. I view the positions as exciting, but a tough road. Doing an academic postdoc would allow me to transition to a fully independent scientist while having some freedom to work on exciting and potentially groundbreaking science. At the same time, I am well aware this is a difficult road particularly if I want to achieve my goal of becoming a principal investigator down the road. I view it as the road less traveled, with way less pay than industry positions, and a struggle to succeed in academia.

Fundamental issues and challenges

The biggest issue facing postdoctoral trainees in my opinion is financial security and being rewarded for your skillset. It's absurd that a first year post-doc with a PhD will make less than a large number of 22 year olds just graduating college and entering the workforce. Moreso, making half or 2/3rds less than our peers who go take jobs working for a large company (Genentech, Kite Pharma, Gilead, GSK, etc). It is in my opinion the single largest driving force that is leading to a loss in the number of PhDs even interested in doing a postdoc. The recruitment seems like an ok process, although difficult to navigate alone. Retention, from what I've heard, can be tough depending on a lot of factors.

Existing NIH policies, programs, or resources

I think there should not be a cap on postdoctoral payment. The postdoc pay should be scaled with living costs, similar to how PhD programs work. Someone in grad school can make the NIH minimum in a cheaper city like Des Moines, Iowa, but grad students in Los Angeles or NYC are payed up ot 35% more than the NIH minimum due to a much higher cost of living. Why shouldn't it be like this for postdocs? Postdocs in NYC or other high cost-of-living areas should be able to get paid 20-30% above the minimum to help account for the additional living expenses.

This does go back to an issue with NIH modular budgets, which for an RO1 has been stuck at the same level for 20 YEARS. $250,000 in 2003 would be approximately $400k today, adjusted for inflation.

Additionally I think more programming and structured mentoring for NIH funded postdocs would help retain postdocs longer and I think lead to an increase in research productivity.

Proven or promising external resources or approaches

From what I have heard, most postdocs love what they do. They just think they should be treated fairly for what they are doing, and payed with respect for their level of intellect and hard work. Job satisfaction would improve greatly with reasonable pay (20-30% increase in pay).

Response 2035

Perspectives on the postdoc roles and responsibilities

An academic postdoc, I believe implies to most people, including me, a transitional position where one continues training for (ideally) a tenure track position. And this training aspect is how employers have implicitly justified the fact that postdocs in most cases are dramatically underpaid compared to the market value of their qualifications.

Fundamental issues and challenges

Tenure-track faculty positions have become increasingly more difficult to acquire, which decreases the value of the training aspect of the job for most people. Importantly, while a PhD is a useful asset for getting an industry job, postdoc experience rarely provides much value beyond the academic track. This problem was recognized some time ago, and everybody agreed that we should do more to encourage students to go to industry if they were so inclined. Thus I find it difficult to understand why we are now all surprised that's exactly what happened, and there are fewer postdoc applicants. If the US biomedical research needs more postdocs, I believe there's no other way than to transform the position such that (after some experience) people who decide to stay on the bench rather than become PIs can do so and get paid like professionals, not like trainees. However, in most cases, institutional rules and salary structures, but more importantly the NIH salary caps are not compatible with such career tracks. Bottom-

line is postdocs are getting paid too little for the hope that it leads to a faculty position, which is probably not going to happen for most of them, and they know it too.

Existing NIH policies, programs, or resources

As an example, NIH could mandate that after the first 3 years, postdocs be offered salaries dramatically higher than their starting one, if they choose to pursue a "professional researcher" track (which could be enforced by e.g. ineligibility to apply for NIH grants as a PI for a defined amount of time). More generally, it is necessary to improve career advancement opportunities of postdocs as well as their financial situation.

Proven or promising external resources or approaches

No response

Response 2036

Perspectives on the postdoc roles and responsibilities

Postdoc position involves working on a project initially with a member of the lab and learn about the field of research and experimental skillsets. Later, the postdoc is expected to successfully lead a project and collaborate with lab members or other labs. The postdoc should be involved in designing project, writing grants, attending seminars and conferences, training new lab members, etc.

Fundamental issues and challenges

Number one challenge is the salary. Postdocs in big cities and suburbs cannot get paid the same. The salary needs to be scaled to the average expense in a given place. Additionally, other benefits and compensation like 401K, HSA, etc.

Existing NIH policies, programs, or resources

More NIH programs should be open to international postdocs.

Proven or promising external resources or approaches

It could be beneficial to form a committee like that of a thesis committee to assess the progress, work load and dynamics between the postdoc and the Principal Investigator.

Response 2037

Perspectives on the postdoc roles and responsibilities

Postdoctoral training adds both depth and breath in my scientific training while forging my career pathway to an independent research program. It is an integral part of my development both scientifically and professionally. I had the chance to try my hands on "running a lab" in a sub-area in my PI's lab to build confidence in later establishing my own independent research lab and program.

Fundamental issues and challenges

While there are many uncertainties that affect the decision in taking a postdoc position, one of the biggest issues is relocation expenses. None of the postdoc opportunities, both for myself and fellow postdoctoral colleagues, was offered a relocation allowance. The relocation expense is a huge burden on perspective postdocs in moving across country and even in times internationally. A cross-country move is at least $2,000 with additional upfront cost of apartment rental (e.g., application fees, security deposits) and living expenses with the first paycheck's delayed arrival 1-2 months after the position starts.

There is no supervision on PIs in matching NIH salary on an annual basis once hired, leaving it up to institution administration/PI. The employee benefits also vary greatly depending on the institution policy in how postdocs are viewed as official vs. unofficial employees. The lack of accountability in securing employee benefits and leaving it up to institutions/PIs put postdocs in extremely vulnerable financial positions, while many postdocs are at child-bearing age with families and partners to support on an underpaid postdoc salary with frequent moves.

On top of these difficulties, international students face additional challenges due to lack of funding opportunities. While it is understandable that federal funding favors supporting domestic research, the

extremely limited options for international students in applying for federal grants put them at additional risk in the power dynamic who rely almost entirely on PI/institutional funding.

There also seems to be limited options of career outcomes for postdocs in my field —mainly in academic settings with few opportunities, resulting in severe competitions among postdocs in securing a position.

Existing NIH policies, programs, or resources

If translational research is of current central interest to NIH, I suggest investing in funding industrial research by allowing and supplementing postdoctoral trainees in industry settings. These environments are more likely to encourage technology transfer that will directly benefit translational research, while enhancing the lived experience of postdocs during training with better career perspectives at the end of training. Once industrial postdoc training becomes more popular, it will likely move academic institutions to become more competitive in securing postdoc trainees with better benefits.

Proven or promising external resources or approaches

European Union has successful models in funding collaborative schemes that require participation of industrial partners. Some of the doctoral/postdoc positions are housed within the industrial partners to foster collaboration with academic institutions. These schemes usually require comparable benefits regardless of the home institution (academic vs. industrial partner) with a great sense of equality

Response 2038

Perspectives on the postdoc roles and responsibilities

I view the postdoc as a stepping stone to my next career stage. For me, I am trying to learn valuable skills that will translate well to a career in industry and establish a track record of productivity in my current role as a postdoc. In a recent discussion with other postdocs, we discussed whether we view ourselves as "trainees" or "employees". Almost no one viewed themselves as a trainee. I see the postdoctoral position as no more a trainee than is anyone else in their career who is trying to be better at their job. For instance, my wife just started her first job as an accountant. She is learning on the job, but she is not a trainee, she is an employee. As such, she is entitled to certain benefits that postdocs rarely enjoy (i.e. higher pay, health, vision, and dental insurance, 4 weeks of PTO, maternity leave, etc.).

Fundamental issues and challenges

Money, work-life balance, and long-term academic career prospects that are not incredibly insecure. Money: there should be cost-of-living adjustments for pay and the "minimum" pay should be increased. For instance, in the Research Triangle area of North Carolina where I live, a postdoc should be getting paid at least $70-75k per year to feel as if they did not completely waste their time getting a PhD. Obviously, that number is much higher in more expensive cities. Work-life balance: currently, this is very individual. My PI's expectations are very fair and allow me to have a life outside of lab. This is absolutely not the case for many other postdocs who essentially live at work. If the NIH can influence labs to not encourage unhealthy work-life, this would make the postdoctoral position more attractive. Long-term academic career prospects: it is no secret that it is incredibly difficult to obtain a tenure-track faculty position in academia or government, and even if you do get that job, grant-chasing leaves one in a very tenuous position. As long as junior faculty do not seem sufficiently supported, people will continue to go to industry jobs instead. As long as industry takes people straight out of their PhD (and pays double what a postdoc does) people will continue to go straight to industry out of their PhD, and labs will be left wondering why no one wants to go to academia.

Existing NIH policies, programs, or resources

In recent discussions with others who are more aware of the debate between NIH and Universities on how to retain / recruit postdocs, it came across quite clearly that both parties (NIH and Universities) wanted to pass the blame to the other side. Specifically, the NIH seems to think that Universities should be doing more to supplement what the NIH is already doing to support postdocs. The Universities say the NIH "standard" pay is $55k, so that's what they pay. If either side is actually serious about recruiting more postdocs, they need to get together and figure out how they can do that. No one is more aware of NIH policies, programs, and resources than the NIH. They should get creative and decide how they can meet the basic improvements requested by postdocs.

Proven or promising external resources or approaches

If you want to recruit valuable people, offer to pay them more money. The NIH will obviously never be able to compete with industry salaries, but if they can pay 75-80% of what someone would earn in industry (as opposed to the ~60% that they pay in my area) I have no doubt that they will get more postdocs. Postdoc salary should also be adjusted at least to match inflation each year. By-and-large postdocs do not care who is paying for this (NIH or Universities), but this is what needs to change. As far as work-life issues are concerned, I see little avenue for NIH to change this through policy (although it could start by not requiring its own postdocs to work long hours for low pay, which I know is the case at least in some NIH labs). If postdocs are paid better though, they will be less concerned about long work hours because at least they are being compensated for that work.

Response 2039

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

I have a 6-month-old son and it is impossible for me to find him a daycare spot. Forget the cost--I can't even get him in! I therefore have to take time off to watch him during normal work hours and adjust my schedule so that he always has care. Most post docs are in the time of the life where they're becoming parents and there is little to no support from a job that requires so much after hours and weekend work. At times it feels like I should just stay at home with him despite all the work it took to get a PhD and how much I value my research.

Existing NIH policies, programs, or resources

I know that there are very few grant sources for non-Americans and as an American, I understand this. Majority of our NIH funding comes from the taxpayers and I would rather use that money to support American scientists who will stay in America. Even as an American it is hard to get funding. Instead, I believe that we should support a system to help grant citizenship to scientists who wish to spend their career in America. This way their training and knowledge stays here instead of going back overseas.

Proven or promising external resources or approaches

Encouraging universities to have daycare connections for parents would be a start. My job also only offers 6 weeks maternity leave which is the bare minimum recovery for a c-section. I had unexpected complications, and my son was born premature. I needed to extend my leave to deal with his health problems and there was no financial support and very little understanding of how leave functions for post docs.

Response 2040

Perspectives on the postdoc roles and responsibilities

My postdoc position is a time to show research-related skills without any pressure from course works or the pressure of obtaining any certificates. At the same time, it is the terminal stage of fine-tuning learning for me.

Fundamental issues and challenges

LOW PAYMENTS: I can't emphasize enough on this point. In 2023 PhDs earning 53-65K/year won't work. We are at least 20-30K behind the per.

Temporary job status: The job security is not there. Please find a way to make the postdoc position a permanent job.

PI's unwilling to specify the job description: Postdocs are assigned to subprojects without any additional payments

Existing NIH policies, programs, or resources

Please increase the yearly salary by at least 20-30K and bring the postdocs under tax exemption for the national interest. NIH can enforce the universities to pay extra money in exchange for department-specific

jobs such as TA roles, coordinators, and lab managers role. In fact, many postdocs does these, without payment from the department or PI, as an addition to their postdoc responsibility.

Please make the position permanent for the affiliated university. For example, a postdoc position can be an entry-level permanent job at a university. Following that the postdocs could automatically be promoted to the university's open job positions.

NIH can introduce auditing the PIs' role to monitor if postdocs are truly assigned to a specific project. The NIH office can establish direct communication with the postdocs a few times a year.

Proven or promising external resources or approaches

I know some universities are offering additional roles to postdocs with extra payments. It will help both parties.

NIH and Universities can involve some industries to support the postdocs as well. For example, industries can give some contact research to the university and postdocs can perform the job with extra payments

Finally, NIH must develop a system for communication with the postdocs directly.

Response 2041

Perspectives on the postdoc roles and responsibilities

I see the postdoc position as a skill gaining and transition time. During this time, I want postdoc to hone the skills learned in graduate schools (methods, grant writing, teaching) and hone their interests. This will give them the ability to transition to an independent investigator type position. I think postdocs have the role of more senior in the lab to graduate students, but are at the same time learning. I have seen abuses of the positions were a PI gives too much "grunt" work or teaching responsibilities. This does not allow for proper development of a postdoc.

Fundamental issues and challenges

I think the biggest challenge of being a postdoc is salary related. It is impossible to ask science trainees to be impoverished for so many years undergrad, graduate school and postdoc. Once you are a postdoc you are often in your late twenties or early thirties and want to start thinking about a family and buying a house which is often not possible. This impoverishment has many detrimental effects. It turns people away from ever doing a postdoc, and leaving science. It discourages individuals from disadvantaged backgrounds from continuing in science. I often see people who come from families with money who can gives extra support or individuals with spouses making a good salary continue, but those without this extra support leaving. Have a wealthy family or rich spouse shouldn't be a requirement to pursuing a career in science. This leads to drop off of good postdoc candidates simply because they can't afford it. It also leads to difficulties after postdoc as you have not built equity or savings for all those years, where non-scientists have been. I think this discourages a lot of people from pursuing academic careers.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

Better salary and benefit support. Housing buying support like is given to military families.

Provide incentives for good mentors to spend time mentoring postdocs of all backgrounds and abilities. Currently, there is no "reward" to mentors for being run a lab that is a good training environment for all.

Response 2042

Perspectives on the postdoc roles and responsibilities

After 5-6 years of PhD training, the Postdoctoral position is mostly waste of an individuals time and young creative age. It is understood academic institutions need Postdocs and PIs also need Postdocs. However, institution hosting a Postdoc must consider the individual as an employee and offer all the benefits they would offer to any of it's employee. For example, employee equivalent matching 401K or 403b retirement

benefits. NIH must be on the phase wise abolish Postdoc Mission and introduce Staff Scientist position with inflation adjusted salary or only allow a three (3) years maximum instead of current six (6) years.

Fundamental issues and challenges

There is NO standard and structure for this Postdoc training program. I am doubtful whether this training is even necessary. The Postdocs are at the mercy of PI or the host institution. After 5-6 years of PhD training one is ready for a real job rather than entering into another trainee position. It is total waste of individual creativity and waste of time, money and life.

Existing NIH policies, programs, or resources

1. NIH must ensure that academic institution hosting a Postdoc must consider the individual as an employee and offer all the benefits they would offer to any of it's employee. For example, employee equivalent matching 401K or 403b retirement benefits. That's not the case in most scenario.
2. NIH must be on the phase-wise 'Abolish Postdoc Mission' and introduce Staff Scientist position with inflation adjusted salary
3. Alternatively, only allow a three (3) years maximum instead of current six (6) years with again inflation adjusted salary and appropriate employee benefits at host institutions that are rich enough to offer match in 401K and 403b benefits.
4. The Staff Scientists should be allowed to submit grants as independent PIs

Proven or promising external resources or approaches

1. NIH should only allow maximum 2+1 (Max) years of Postdoc if not abolishing it immediately by replacing with Staff Scientist position.
2. Standardize and structure the 2+1 (Max) training like MD folks have ACGME type 2 years fellowship post MD-residency with outcome expectations from institutions and PIs in terms of job placement and training.
3. The structure of a 3 years Basic Science Postdoctoral Fellowship should be standardized and professional like any ACGME Fellowships for MD folks.
4. The Staff Scientists should be allowed to submit grants as independent PIs when 'ABOLISH POSTDOC MISSION from the Nation of USA' is achieved.

Response 2043

Perspectives on the postdoc roles and responsibilities

I went into an academic postdoc to expand my skills set but the graduate students in the lab were territorial of the ongoing projects and samples. Though I was able to get a postdoctoral fellowship to have a decent pay check, the low pay for academic postdocs was a hinderance and gave me pause as an international person. Additionally, the postdoc did not give me as many opportunities to situate myself strategically for the next academic or industry position (paper writing teams, grant writing opportunities, teaching opportunities, etc.). One positive was that I was in a lab that was closing. This gave me many opportunities to develop my own connections leveraging my PI's connections. I have know 2 recent female postdocs who were at research centers and moved up to assistant research professor due to the needs of the research center. These trainees did not receive adequate mentorship from their established mentoring teams which left them drained, frustrated, and feeling that their quality of life was not good so they left academia. One of these trainees had a K award that she walked away from.

Fundamental issues and challenges

Low pay and often a lack of health insurance is a hinderance to all three aspects. Poor mentoring and a lack of mentoring has also become a big hinderance to retention and quality of life of postdoctoral trainees. The low number of academic positions to apply to at the end of a postdoc decreases retention and quality of life as many people then have to do additional postdocs. Having the standard often be a 5 year postdoc to be able to get an academic position should not continue to be the standard as if decreases recruitment, retention and quality of life.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 2044

Perspectives on the postdoc roles and responsibilities

The postdoctoral trainee is a position where a doctoral graduate gets training for becoming an independent researcher and eventually becomes an academic faculty member. This position provides the necessary training to expand research experience, lab management, training lab members, obtaining funding, and utilizing them in an effective way. It is a very crucial phase in the field of academia. Therefore, it's very common to get overwhelmed by work stress as a post-doc.

Fundamental issues and challenges

No response

Issues and challenges for post-doctoral trainees:

1. The post-doctoral trainee is a temporary job position and depends mostly on the PIs and grants. Therefore, the position does not provide any job security.
2. There is no specific job responsibility for the post-doc which leads to an excessive workload that harms their physical and mental health.
3. Compared to the work pressure and mental stress, the salary is very minimal for post-docs. Whereas similar or even less qualified individuals in a non-academic profession earn way higher.
4. For international scholars, most academic institutions do not provide the option for permanent residency which leads to uncertainty in the immigration status of the post-docs.
5. Most of the post-doctoral grants offered by NIH or other sources have a citizenship requirement which makes it very hard for international scholars to get funded.

Existing NIH policies, programs, or resources

Policies that could be modified, expanded, or improved:

1. Currently the postdoctoral trainee is a temporary position according to NIH. The situation could be modified by establishing the postdoctoral trainee role as a permanent full-time (40hr/week) position with specific job responsibilities that is partially authorized by the academic institute and NIH. If any individual is working after hours, they could be given overtime payments on an hourly basis.
2. The salary of academic postdoctoral trainees is approximately $20000-$30000 lower than the salary of a non-academic position with similar qualifications. The salary could be increased for the academic post-docs to make it equivalent.
3. Academic institutions could provide services for permanent residency or stable visa status to international scholars.

Proven or promising external resources or approaches

1. The salary of a postdoctoral trainee could come from multiple sources. For example, having an additional role in the academic institute or in the associated hospital from where they will get a salary which altogether will increase their income.
2. NIH and other funding sources could extend their eligibility requirements for international scholars with valid visa status.

Response 2045

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

No response

Existing NIH policies, programs, or resources

Abolishment of T-grants for postdocs and replacing them with more F-grants: an individual fellowship obtained by the postdoc has a much more positive impact on career development than the one given by the institution. An individual fellowship strengthens the postdoc (psychologically, because it was an effort to get it and because someone (NIH) is supporting and believing in them) and strengthens the postdoc's position within the institution. T-positions are part of politics within clinics and departments and have little potential to accelerate postdocs' development.

I imagine that F-grants are much more effort for NIH than T-grants, due to the evaluation process, but it would be beneficial for postdocs and research in general if more postdocs went through this process. This evaluation could maybe be a bit simplified to reduce the effort.

Proven or promising external resources or approaches

No response

Response 2046

Perspectives on the postdoc roles and responsibilities

I thoroughly enjoy science and pushing the boundaries of knowledge, it's an extremely rewarding job and intellectually stimulating. I also enjoy being a mentor and guide to graduate students (both PhD and MSc) and helping enthuse others about science. To be a postdoc is to be doing the groundwork for the advancement of science under senior leaders of their fields.

Fundamental issues and challenges

I think the most critically inhibiting factor as a single person, is the postdoctoral salary and career progression opportunities. Whilst I would generally say my quality of life is good and I maintain a good work life balance through careful budgeting and time management, the salary does not even come close to be commensurate with both experience and the unequivocal expectation of putting in vast amounts of overtime hours, especially in more expensive cities on the east and west coast. There are so many higher paying jobs that will readily hire PhD graduates and postdocs for double the salary and a standard 9-5 working schedule. Many other entry level jobs that require only a BSc (or less) easily pay the same or more, especially in large cities like Boston and New York. Sometimes, the love of science is not enough to overcome this, especially with the snail-like pace of salary progression and paucity of tenure track positions. Excusing the salary by saying the postdoctoral fellowship is training is truly not good enough as many other jobs will pay much higher starting salaries whilst also training employees with valuable skills.

Existing NIH policies, programs, or resources

Increased engagement with industrial partners would be of benefit to offer a more tangible reason to stay in a postdoctoral position if a guaranteed job in industry would be provided at the end, as often there are far too few tenure track positions for the number of postdocs. It would incentivise people to bring projects to completion before suffering from burnout or job dissatisfaction.

Proven or promising external resources or approaches

No response

Response 2047

Perspectives on the postdoc roles and responsibilities

A postdoc is a wonderful opportunity to get additional experience (technical skills, professional development, soft skills) and increase research productivity. I moved from a smaller R1 (newly designated) institution to a well-established institution with an NIH-funded center, so the resources and experience have been an incredible contrast. I understand the postdoc position as an opportunity to expand your professional depth and expertise, so you are more likely to succeed as a PI with an independent lab.

Fundamental issues and challenges

Postdoc positions used to be 1-2yr positions and now are more often 4-5yrs, so the poor pay is really challenging. This is especially true for those who have had to take on loans to get through graduate school due to poor stipends, and those who are not in two-income households or who have family financial support for graduate school or postdocs.

The expectation that postdocs apply and receive a K99 in order to be competitive for faculty positions makes it even more likely that you will need to spend at least 4yrs in a postdoc. Also there *seems* to be an expectation that K99's must be submitted twice in order to be competitive. An additional grant cycle is a considerable amount of time when there is a fine balance of meeting the less than 4yr of postdoc requirement and the implied you must be the absolute best and most competitive to receive the grant. The K99 is presented as more training needed to move forward, but in contrast, it is also seen as an incredibly prestigious award only the best postdocs qualify for. This is counterproductive as the postdocs who need the additional training will likely not receive the grant, and those that are already at the top of the postdoc pool will receive additional support training, and interest from institutions hiring faculty. IF the K99 is indeed supposed to recognize and support top-tier postdocs, the requirement of presenting the additional training as NEEDED, should be revised. We could all (literally every scientist everywhere) benefit from additional opportunities to pursue cutting-edge techniques that expand our skill set.

Existing NIH policies, programs, or resources

Reframing the K99 and K01 grants. Universities find the K99 incredibly appealing as you are able to bring funds to a new institution. Perhaps we should have the option of only writing an R00 as prospective grants to be taken to a new institution, in contrast to the K99 requiring more training, or a K01 that is intended to be written after settling at the new institution.

Proven or promising external resources or approaches

Response 2048

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

As an intramural postdoctoral scientist, I am NOT eligible for the NIH loan repayment program. As I am not classified as a federal employee, I am also NOT eligible for student loan repayment program (SLRP) granted to full time employees as a way to recruit or retain them. This seems like a large oversight as postdoctoral fellows are just entering loan repayment. I love NIH and would love to stay in my postdoc, but feel I cannot afford to do so once the temporary halt on repayment is lifted.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 2049

Perspectives on the postdoc roles and responsibilities

Postdocs are highly skilled and trained individuals that have critical roles in academic labs. Their roles are varied and depend greatly on the lab and the postdocs career aspirations. However, the key thing that differentiates postdocs is that they know how to approach a problem scientifically. They often bring important techniques and skills with them that don't otherwise exist at their destination, or come to learn new techniques and apply them to their own ideas. They can work relatively independently, but need support and additional training in leading projects, budgeting, strategic decision making, writing, applying for funding, or other scientific-adjacent skills.

Fundamental issues and challenges

After finishing their graduate degree, postdocs are extremely skilled workers, and yet postdocs are offered very small salaries with time-limited appointments. Expectations of time and commitment are high, but postdoc jobs don't return the favor. Postdocs are expected to be time-limited and there are no guarantees of any particular job at the end. Given this, and the alternative of a highly paid, high potential for career growth position in industry or consulting, it's no wonder it's harder to convince graduating students of pursuing a postdoc. Compounding this problem, postdoctoral training often comes at a certain time in a person's life, where they might be starting/contemplating a family, and otherwise transitioning to a non-student lifestyle. Furthermore, highly trained peers in other fields are doing much better at this stage of life than biological sciences postdocs—friends that went to law school, medical school, or business school are all more advanced in their careers and have greater job security than equivalent positions in academic science. You can not even blame postdocs for feeling discouraged by this prospect and considering other career paths, it is a tough life choice, and without the ability to apply for or supply higher salaries, PIs are hard-pressed to provide a competitive/living salary. We expect postdocs to take postdoc positions out of their own drive and passion, and to tolerate the disadvantages of postdoc life in exchange for vague career training. Its no wonder academia is becoming less and less attractive.

Existing NIH policies, programs, or resources

Salary caps for postdocs should be increased, and there should be mechanisms to allow PIs to apply for supplemental funding if negotiated salary rates are increased mid-award. At my institution—[redacted for anonymity]—the postdoc union negotiated a higher salary for postdocs than what is allowed for postdoc fellowships, putting PIs on the line for the the increase out of discretionary funds (IF they have them). This is a huge problem, and it creates a perverse incentive for PIs to oppose postdoctoral union initiatives, or even just institutional decisions to increase salaries.

Proven or promising external resources or approaches

Honestly, I think it comes down to money/salary support. And if it can't be money—then there has to be something special about postdoctoral training—better benefits or job security/training/placement. Those initiatives would have to be done at the institution level. There are also not enough academic positions, so another thing that would help is eliminating tenure/establishing funding term limits so more positions would be available for new people.

Response 2050

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

No response

Existing NIH policies, programs, or resources

All junior scientists need to receive science communication training as part of their NIH award.

Proven or promising external resources or approaches

Many science-communication training opportunities exist, but these need to be encouraged through funding.

Response 2051

Perspectives on the postdoc roles and responsibilities

Post-docs have many essential roles within the laboratory space. We can help to train students, optimize and create protocols, and write papers/grants for our mentors. I think they are essential to the advancement of science as most PIs can no longer tell you the nitty gritty details of an experiment—which are usually the most critical part for success and reproducibility. I also think that post-docs are not given enough freedom for themselves to create their own projects—a lot of this having to do with the overall funding structure of grants. Currently, PIs have projects which are largely accomplished by post-docs and graduate students. However, if a post-doc wants to try to apply for other funding, they have to start a new

project to show separation from their mentor, but there is rarely any "extra" funds for a post-doc to try to carve out their own research. This greatly stymies a post-docs ability to use their training and creativity to try to carve out their own niche for the future. Post-docs are also largely used in every area of research from basic wet lab, paper/grant reviews, or grant writing and are not able to receive credit for these contributions. This also takes up time and does not allow for proper recognition. It also can create an environment that produces burnt out post-docs that are less productive and interested in science as a whole since it is a lot of work in many different avenues with very little credit, recognition, or pay changes.

Fundamental issues and challenges

I think the biggest issue is payment. The pay level for post-docs has not or has barely changed in the past decade. This is unacceptable. There's also usually a miscommunication of expectations as there is a mix of cultures that all collaborate within a lab, and expectations from some countries can be very different than expectations here. This can create an unfair lab environment. There are also people on different funding mechanisms, and so one post-doc can make 10-15K more per year. The funding discrepancy is very apparent when comparing to similar jobs in industry where you can make double for doing a very similar job, there is no incentive to stay in academia. Furthermore, post-docs usually receive 1 or 2 year contracts. This can make it difficult if you're trying to buy a house or start a family. To buy a house where I live I had to show 4 years of previous employment and 3 years or future employment from my current employer. If I would have had a 1 or 2 year contract this would not have been possible. I also think post-docs are not as respected as they should be. Most PIs will look at post-docs are just labor. Post-docs are the future of academic research, so treating them as glorified techs is not the way to maintain them in academia. If treated like a glorified tech, I would have left to a tech's pay in industry—which is almost double my current salary.

Existing NIH policies, programs, or resources

Timeline restrictions for grants has to change. As a female scientist, if I wanted to have kids before applying for an NIH grant, it would have been almost impossible. Giving a 1-year extension max is not sustainable. As we're about 50:50 at the post-doc level and then ~15% as faculty, this has been a major reason among my friends. For example, if I wanted to have a child in my first year as a post-doc for age concerns, then I'm pregnant for 9 months, assuming no complications there are certain chemicals and reagents I should not be around which can affect my work. Then after the baby is born, I'd have maternity leave (ideally at least 2-3 months). During this time there are other physical demands of the woman that the partner cannot take care of. There are also changes in mental state during and post pregnancy. If I want to have a second kid, this does not affect the total 1-year extension. If the requirement for a grant, like a K99—which is almost necessary to have to get hired at a good institution—has a 4 year post-PhD requirement. So, if I did research for 1 year, got pregnant once or twice, a 1-year extension is not going to bring me to the same level as a man who has been continuously working on his project for 4 years with no physical or mental changes because of hormones or pregnancy complications. If you truly want to keep women in science then change these policies. A new "short" K99 has been introduced, why not include a longer one? Also more post-doc funding in general that is not time dependent. People learn, grow, and discover at different rates.

Proven or promising external resources or approaches

I think looking at the structure of other companies that deal with STEM or tech development. In these programs they have protected "creative" time. I also think having funds available either within the R01 mechanism for "creativity" or project branching, or outside of this for post-docs to develop projects is essential. I know personally I have written grants to support the research I wanted to do outside of the projects that were required of me. This has been really challenging and something that I don't think all PIs would allow as they usually believe all of your time should be spent helping their career. This again gives no recognition and no personal grants. While papers have post-docs as first authors, the general community still looks at this as the work of the last author and his group. While true, it makes it very hard for post-docs to feel appreciated/valued or chances for career development. As stated above, if more post-doc grants are created, they should not have time requirements, or have some sort of sliding scale of 1-3 yr, 3-5 yr, and 6+. Papers can take 1-2 years to get published which again is almost punishing people who want to try for a higher impact paper. Post-docs need these higher impact papers for their careers—according to universities. So, overall I think really taking into consideration the impact of having children—a 1-year extension is not sufficient—and having more opportunities for "creative" time for post-docs to develop independent careers is essential if you really want to keep people in academia.

Response 2052

Perspectives on the postdoc roles and responsibilities

It means an opportunity to expand your knowledge and acheive fund to become independent and build your own research lab.

Fundamental issues and challenges

Low salary and lack of job security are the fundamental issues that make the experience so stressfull.

Existing NIH policies, programs, or resources

The minimum salary that is set by NIH is rediciously low. For those who are living in Boston this salary is peanuts.

Proven or promising external resources or approaches

I think increasing the NIH base salary should be a good start to increase job satisfaction.

Response 2053

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

The salary is easily the biggest problem. In a city like Boston, a decent 1 bedroom house costs $2500/month. The salary after tax deduction is $4200/month. If you have a dependent spouse and child, it is impossible to live on this stipend. The cost of childcare is $2000/month. So rent+childcare alone is more than post-tax salary. Salaries need to be adjusted for cost of living in the big cities. In a city like Boston, salaries must start at $90,000/year. After acquiring the kind of expertise that we do in our PhDs, living paycheck-to-paycheck or building up debt just to pay for living costs is not sustainable. With such limited availability of faculty positions, industry offers are much too tempting to continue being a postdoc and struggling with basic living.

Existing NIH policies, programs, or resources

Proven or promising external resources or approaches

No response

Response 2054

Perspectives on the postdoc roles and responsibilities

To me, the postdoctoral position is absolutely crucial for finding a research niche and obtaining experience seeking funding.

Fundamental issues and challenges

In Washington state, we have a new law that requires over $65K as a minimum wage for all exempt employees and this figure will escalate to over $90K by 2028. As a faculty PI, I am extremely supportive of postdocs making a more livable wage (especially with the high cost of living in Seattle). Unfortunately there is just not a solution for bridging the gap between our research budgets created years ago and these new salaries. Moreover, NIH stipends for postdocs on F and T awards are much lower than our state minimum now, but my institution is not requiring that these postdoc salaries get raised—so we have a lack of parity where those postdocs on research project grants are making more than those postdocs on stipends even though they are working side by side in the same lab. I worry that there will be a disincentive for postdocs to write F awards (or to enter T32 programs). This is also becoming an issue in recruiting junior faculty to my institution because they are very worried about how they are going to afford to pay for postdocs in the lab.

Existing NIH policies, programs, or resources

I would like to see NIH increase all postdoc stipends to be more in line with states that have increased postdoc wages (and/or to consider geographic location in the stipend amount). Other resources that are particularly requested by postdocs is relocation and housing expenses. Perhaps programs could be modified or developed to help address this need.

Proven or promising external resources or approaches

No response

Response 2055

Perspectives on the postdoc roles and responsibilities

The postdoc position is a training ground to gain further experience at the bench, learn new expertise, while narrowing down the central theme that will carry an independent research career.

Fundamental issues and challenges

Overall, Postdoc are SEVERLY underpaid! This is the #1 fundamental issue. Living in NYC at [redacted for anonymity], our starting salary was $58k/year. This is so low considering current salary ranges for even unskilled jobs. Further, Postdoc live in an incredibly precarious reality, and are under tremendous pressure to publish or perish, while at the same time asked to mentor PhD/rotating students, review papers, maintain lab environments, apply for grants, ,ecc. It is not surprising that people are living on mass for the private sector. This is a huge problem for the future of scientific research in America.

Existing NIH policies, programs, or resources

1. Provide greater funding to in all NIH grants: and increase the NIH-payline for postdoctoral training
2. K99 grant application are SO stressful to meet (due to the 4-yr requirements post-PHD, which have been completely highjacked by Covid). Again, the NIH has now removed all support/additional COVID time that was initially provided.
3. If you want us to mentor student, why don't you make this a central aspect when reviewing applications?

Proven or promising external resources or approaches

Pay us more, provide more support and more grants!

Response 2056

Perspectives on the postdoc roles and responsibilities

Postdoctoral training is TRAINING after PhD or MD training. For PhDs, it should broaden the trainee's scientific horizon and enable the trainee to pursue important problems that transcend their PhD training. For MDs, the training may need to incorporate more fundamental elements that PhDs receive during their predoctoral training.

The duration of postdoctoral training should be three years, or so. Long enough to allow the trainees to embark on and complete an important project that will enable them to advance their career, short enough to allow the trainee to begin their independent career while they still possess "the arrogance of youth" and are excited about pursuing their own, hopefully iconoclastic research—or other activity (start-up, whatever).

A key aspect of postdoctoral (as well as predoctoral) research training is that the trainee is "playing with other people's money," this encourages risk-taking and the development of new methods—and enables them grow as scientists.

Too long training, however, will be demoralizing, and work against the career development of the trainee.

Fundamental issues and challenges

The key challenge will be to change the current system, which has been developed by old (usually white male) scientists to benefit old (usually white male) scientists. As one of my mentees, who recently had

begun an independent career recently told me: "I am not sure I can recommend this training path/career, it is a Ponzi scheme." I could only agree, we are in the process of killing the goose that lays the golden eggs.

We have long been aware of the rightward shift in the distribution of NIH grants vs. PI chronological age, which is a definite disincentive to begin an academic career.

NIH needs to provide more information about the more subtle aspects of research funding that provides better insight into the support going to junior and senior scientists. Having this information will guide decision-making and might make it easier to implement difficult policies because the problems will be out in the open. Also, following up on the analysis Jeremy Berg did many years ago, what is the marginal return on research funding to very large labs. There needs to be a discussion of the optimal research budget—and the novelty/importance of research done in very senior labs.

Senior PIs who completed their PhD in five years, or so, now expect graduate students to "hang around" for six-to-seven years, if not longer. They tend to argue that the trainee needs to have an article published in one of the vanity journals in order to get a good postdoc or job—forgetting that they were successful just publishing in the high-quality "professional" society journals.

For NIH to make an impact, it will be necessary to have more data that truly show what is going on, that will provide insight in the underlying problem(s).

Existing NIH policies, programs, or resources

First, institute funding policies that would encourage senior faculty to step back and let the next generation run the show. Some ICs already have such policies in place.

Second, repeating what I write above, have an in-depth analysis of how support an investigator should receive.

Three, consider whether it may be possible to limit the number of years a PI can fund a trainee on their RPGs, which might shorten the length of the postdoctoral trainee's wandering in the career Valley of Death because it will be in the PIs interest to promote their trainees' independence and independent careers.

There will not be a major influx of new money, the only stable solution to the problems that postdoctoral trainees face will be to create room at the top. If we do not create this room, the best trainees will disappear. They may decide to not to apply to predoctoral training programs, there are many other exciting careers. They may also decide to forego academic careers after their doctoral (and, maybe, a few years of postdoctoral) training. That is not necessarily bad over the short term, because they may do great things in startups or more mature companies. But it will be bad over the long term because it will impact on the future training of young scientists who are interested in working on important problems. The key here is IMPORTANT, interesting is not enough.

Looking back over fifty years, the bureaucracy has become a lot more cumbersome. NIH and other institutions need to examine what any regulatory requirement is going to accomplish. If NIH asks for a piece of information, they need to do something with that information. If the information will not be used for quality control or some other identifiable use, it should not be collected.

Proven or promising external resources or approaches

As should be clear from what I have written above, there has to be systemic changes before one should consider these questions.

I also want to add that the problems are so large/complex that it makes little sense to limit the responses to 300 words.

Response 2057

Perspectives on the postdoc roles and responsibilities

This is a senior research role. Main responsibilities include conducting higher-risk (perhaps more complicated) research projects and mentoring graduate students, techs and undergrads. This role also should focus on teaching you how to be an effective mentor and scientist at the same time.

Fundamental issues and challenges

Work life balance is not respected. Post docs work long hours, probably everyday for very little pay. It is time for the NIH to compete with funding/salaries which genuinely compete with industry. Pay is the number one issue with recruiting and keeping post docs. Additionally, there is a lot of abuse that can occur from mentors not having their best interests in mind.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 2058

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

The biggest question comes down to finances. Every time that I have thought about quitting (and there have been many), it is because after paying off 350k in student debt, it is hard to start a family with no savings while earning at the 10th percentile in the field you trained to work in (as an MD researcher). Every life event means extra weeks of moonlighting such that there has not been a single year in the past 9 that I haven't had to moonlight or take 2nd or 3rd jobs to make up an extra 30-50% of my base salary as a researcher (I currently have 6 regular sources of income, while NIH pays the majority of my primary source). That extra work leads to years of compounding burnout, and at some point you have to realize you could work a quarter the hours for 2-3x the salary, and that no amount of scientific curiosity will resolve that. If you want to retain researchers, there needs to be

a) reasonable parity of salary between NIH grant supported researchers and the industry norm (e.g. must earn at the 40th percentile for academics in field at rank in US region, or something similar—perhaps a requirement that the NIH salary cap be applied), and

b) stronger support for loan repayment that is both commensurate to the real burden of student debt and is not contingent on secured future funding (i.e. can receive despite not having several years of secured funding).

Existing NIH policies, programs, or resources

NIH loan repayment amounts are laughably small and importantly are taxed. Getting an extra $35k off my loans would have meant

Proven or promising external resources or approaches

No response

Response 2059

Perspectives on the postdoc roles and responsibilities

Roles/responsibilities are reasonable

Fundamental issues and challenges

NIH F32 payscale is low vs what we can make working (fewer hours) in industry. This makes it very unappealing to remain a postdoc if extreme events occur (health issues, having kids, etc.).

Existing NIH policies, programs, or resources

Overall, I think NIH training is good

Proven or promising external resources or approaches

Look at industry. What is working to keep people at biomedical companies, tech co mm panties, etc.

Response 2060

Perspectives on the postdoc roles and responsibilities

Postdoctoral position is considered a training for transition to an academic career. Underpaid and overworked work environments, with minimal protection of time and effort.

Fundamental issues and challenges

After several years of PhD, where rigorous training occurs, the postdoc position is still considered another level of "training", hence postdocs are not considered employees, while they are clearly not students like graduate students. Unfortunately, this leads to another 5+ years of extensive and rigorous working without the appropriate benefits, nor experience/assistance that helps transition to a permanent position, neither is the experience counted if one steps out of an academic setting. There are no positions to absorb trained manpower into research institutions. Faculty positions are limited and intake is restricted. International postdocs (who make up majority of the population of postdocs) are faced with incredulous challenges in terms of immigration and Visa issues. Despite all the training, qualifications and qualities to be employable, VISA restrictions discriminate against them, since institutions find it cumbersome and expensive to process and sponsor visas like H1B.

Existing NIH policies, programs, or resources

- NIH policy should include matching retirement benefits for postdocs. This is absolutely essential.
- It is highly discriminatory and dismaying that such highly trained professionals are not paid their worth and not provided with benefits that all other employees with much lesser qualifications are earning because they are employees and not trainees.
- 4 weeks of vacation time is not always used each year due to various reasons, either it should be permitted to be encashed (like how regular employees receive) or allowed to be carried over.
- There is no overtime payment for extra hours and days that one works.

Proven or promising external resources or approaches

Instead of having postdoc positions as training positions that leave them hanging in search for future jobs, why not convert these to permanent Scientist positions. This will ensure productivity and retention of talent and ensure research occurs smoothly.

Response 2061

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

1. Salary vs responsibility is disproportionate. The postdoc salary (and graduate student salary) is unlivable for many individuals—presenting even greater barriers to individuals from low SES backgrounds, diverse racial /ethcni groups, etc. from pursuing these positions.
2. Mental health: Many training environments (and faculty environments) make exceptional people feel inadequate.

Existing NIH policies, programs, or resources

Increase pay for postdocs/graduate students. To do that, the amount of money that can be allocated for research awards needs to be increased! NIH is not keeping up with inflation/increasing research costs!

Proven or promising external resources or approaches

Require mental health and wellness training for all institutional training and career development grants awarded

Response 2062

Perspectives on the postdoc roles and responsibilities

Conceptualizing projects, performing experiments, writing grants, managing technicians and students, develop professional skills through courses. To me a postdoc is a continuation of your PhD, with an emphasis on moving towards independence.

Fundamental issues and challenges

For international postdocs moving countries is very hard. Relocation costs are not refunded, so everytime I move to a different position I have to start over with no savings. I dont have parents who I can fall back on financially, so I think many people considering a carreer in acadamie just cant afford it. On top of that, we have often times already spend over a decade studying, obtaining an undergrad, masters, PhD, after 10-15years of studying you deserve to be able to afford your own appartment. I dont know a single post doc who can afford reasonable housing.

Existing NIH policies, programs, or resources

Provide salary ranges based on the state/city the postdocs are based. Provide relocation costs for international postdocs. Provide an F32 program or equivalent that J1 visa holders can apply for. Establishing yourself as a foreign academic in the US is much more difficult due to restricted access to funding.

Proven or promising external resources or approaches

Many unveristies in Europe cover relocation expenses, this should be included in the funds that NIH provides. For example:

https://vu.nl/en/employee/fringe-benefits/remuneration-of-removal-expenses-information

Response 2063

Perspectives on the postdoc roles and responsibilities

I have always viewed the postdoctoral position as something of a scam. Looking back to the 1950s, when resources were more abundant and the pipeline for training was not yet well-established, most would agree that it was uncommon for anyone completing a PhD in the biomedical field to pursue a postdoc. Rather, it was more common to be considered independent, and to immediately launch one's own laboratory. Since then, arguably due to too many PhD graduates chasing too scarce resources, the tradition of requiring a postdoctoral position, sometimes multiple postdocs, has become firmly entrenched.

Although there are benefits to the postdoctoral trainee, I personally do not think that it makes sense for someone who should be independent in their research to gain still further training —when he or she crosses the threshold to become an independent investigator, acquiring new skills would be as simple as hiring someone else to do the work in their lab.

Fundamentally, the current postdoctoral training paradigm assumes that post-doctoral training is necessary, and does not acknowledge that the goal position of an independent investigator is one of a manager, overseeing the productivity of other members in the lab. As such, it does not do the best job of facilitating PhD graduates to transition to a role of management, but still assumes he or she will do all the work with her own hands, and rarely provides sufficient funding beyond the salary of the postdoctoral researcher to hire help.

Fundamental issues and challenges

Despite its best intentions, I would argue that the actions of the NIH have further entrenched this paradigm by creating "career development awards" which may cover the salary of a postdoc but do not provide sufficient additional funds to support 1.0 FTE of a research assistant, or to fully cover the cost of research, and firmly position the postdoc as a trainee under the guidance of another independent investigator. To be sure, these awards are much needed and better than nothing, but they also perpetuate negative aspects of the paradigm I have described, and need to be reimagined.

For MD/PhD physician scientists, who already devoted substantial time to receive PhD training, in addition to residency, and fellowship training, the prospect of spending another 5 years in a "training role" could

not be a more potent recipe for burnout. Although physician scientists are generally paid better than PhD postdocs, it is still insulting to them, who are in their 40s, have faculty positions and act as attending physicians on hospital services with many hands to carry out hospital business, to pretend that they are a trainee. Many of these scientists could snap their fingers and find a position in industry that respects their intellectual contributions and pays 2-5X more, or simply give up research and increase their salary through clinical volume. Having seen many of my friends and colleagues face this decision and exit basic research, I can personally attest that it takes exceptional fortitude to stay the course.

Existing NIH policies, programs, or resources

I think that the role of the post-doc needs to be reimagined. Every moment of a postdoctoral position should be filled with the purpose of preparing the postdoc for independence and lab management —not some sort of purgatory where they gain skills to take to the next postdoc, or labor as sharecroppers under an established investigator who takes credit for the work. We should start considering them to be mini principal investigators--we should call them postdoc investigators, rather than postdoc trainees, and the awards to support them should not be "training awards" but named differently to acknowledge their burgeoning independence.

The budget for post-doc awards and career development awards (or administrative supplements to these awards) should be increased to allow postdoc investigators to support 1.0 FTE of a research assistant, in addition to existing funds for research and salary. The market rate for this would be ~$70K after fringe. The salary for non-clinician post-docs should also be drastically increased.

Any work generated by the post-doc investigator should be considered a collaboration with that of the mentor PI. Post-docs should be allowed and encouraged to represent their NIH-supported work as independent of their mentor, and NIH documents should require PIs to attest to this and forbid them from submitting R01s or other NIH grants using data from the same NIH-supported work unless the post-doc investigator is included as a co-investigator.

They should be allowed to form independent "research groups" within the lab of their mentor. We should support these research groups to grow into independent labs. The IDC rate should be increased substantially to cover this additional overhead. The academic institution should acknowledge research groups and their post-doc investigators as independent. This would overturn established precedent that PIs have the final call on decisions related to the work.

Proven or promising external resources or approaches

Not sure.

The salary needs to be drastically increased--I currently support two full-time staff, and I was shocked to find that their salaries are about the same as the starting salary of a postdoc at our institution. On the one hand, although I am considered a post-doc by the NIH, I should be able to hire postdocs to work for me if I have the funds, but this is not possible because nominally I am just a "trainee" in the lab of another investigator. On the other hand, it is surprising that someone with a PhD and intellectual independence who could carry out a project independently would be paid the same as a research assistant who never went to graduate school and requires training and 100% supervision.

These economics just don't make sense —the best most qualified labor can only be hired by established investigators (not me), but the salary rate is severely suppressed with respect to the market for PhDs in industry, throttling supply, but NIH grants do not support higher salaries.

Response 2064

on the postdoc roles and responsibilities

The academic postdoc position is, to me, supposed to provide a training experience that serves as a springboard into a faculty role. It should provide sufficient independence that postdocs are able to design and execute their own projects, on their timelines, with support and feedback from faculty mentors. In reality, I think faculty members generally behave as though most of their postdocs are cheap labor for generating data in support of their grants.

Fundamental issues and challenges

I think many postdocs and graduate students have come to view postdoctoral training as exploitative labor, and this will continue to affect recruitment and retention of postdoctoral trainees moving forward. Not only are postdocs not paid fairly, but they exposed to toxic work environments with little or no institutional support. Why would anyone imperil their financial future, not to mention their final few years of fertility, to work as a postdoc in this "ecosystem"??

Existing NIH policies, programs, or resources

Force institutions to pay postdocs fairly, with consideration towards both current economic conditions and the level of education and training postdocs have attained. Which is to say, at the same levels that intramural postdocs are paid at the NIH.

Proven or promising external resources or approaches

Paying postdocs fairly!!!

Response 2065

Perspectives on the postdoc roles and responsibilities

A transition position between grad school and the job market.

Fundamental issues and challenges

Salary, uncertainty of the future, status, titles are unappealing, risk

Existing NIH policies, programs, or resources

Salary grid is lower than similar positions in the private sector

Proven or promising external resources or approaches

working environment and job satisfaction

Response 2066

Perspectives on the postdoc roles and responsibilities

assignment to a funded project of a PI relevant to a technique or the specific area of research from the postdoc's graduate thesis, submit publications quickly

Fundamental issues and challenges

Low pay, harsh work environment (long hours, competitive roles), top priority of publications

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 2067

Perspectives on the postdoc roles and responsibilities

both a job and a training position.

Fundamental issues and challenges

We should have had regional postdoc salaries for at least the last 30 years. cost of living in the Bay Area, Southern California, New York, Boston, etc. is wildly different from Alabama and Iowa. Postdocs in some regions are barely able to pay rent, in other areas they are able to buy condominiums. Many federal agencies use regions rates for employment and other costs (e.g. travel per diems). Not doing that with postdoc compensation is absurd. The people most impacted are from economically disadvantaged

backgrounds. The NIH says it wants to diversity the scientific workforce, but until they acknowledge economic barriers to being a postdoc, those are just words.

Existing NIH policies, programs, or resources

Just pay them at regionally appropriate rates. I doubt the NIH can effectively provide programs and resources, leave that to the PIs and institutions.

Proven or promising external resources or approaches

If you pay $1 a year, you'll only get people who benefit from generational wealth. If you paid $1,000,000 people would break down the doors to get those jobs. Between those numbers is some function that will look different for ecumenically advantaged versus disadvantages potential postdocs. The function will also look different for low and high cost of living regions. Anyone who think about it for a second knows that. Are we willing to reflect that knowledge with policy, or do we keep our heads in the sand?

Response 2068

Perspectives on the postdoc roles and responsibilities

A post-doctoral position to me is short-term (1-3 year) position meant to allow you to independently develop a project under the guidance of the PI. A post-doc position is helpful for further developing scientific skills after graduate school as well as preparing to become a PI.

Fundamental issues and challenges

I currently plan not to do a post-doc because after approx. 5.5 years of graduate work, another 3+ years of making very little money while working very hard with long hours to then needing to face tough competition for funding and a position as a PI is not appealing. In industry, I can expect to make six figures right after I finish my PhD without the need for a post-doc. Also, I have a partner who is also a graduate student, so we would need to find post-docs and eventually academic positions within the same or neighboring institutions which seems daunting. I would like to settle down and be able to buy a home and start a family, which I feel like I have already pushed off for my graduate work, and I don't want to try to juggle that while doing a post-doc.

Existing NIH policies, programs, or resources

I'm not entirely certain. I think pay increases for post-docs would help as well as improving the work-life balance and increasing the attention to building skills for industry as well as academic careers.

Proven or promising external resources or approaches

No response

Response 2069

Perspectives on the postdoc roles and responsibilities

an academic postdoc is simply extended graduate school but now you are expected to apply for and obtain your own funding.

Fundamental issues and challenges

Postdoc research now lasts 5 years so the average age is 30-35. If you're female and want kids this is the only opportunity but there is little support for maternity leave and child care during a time when you are supposed to be highly productive. Securing a job after your postdoc depends on publication record (which is not completely in your control) and funding to take to your new academic instuition (absolutely not in your control). Working in industry will pay more and provide better benefits. academic postdocs select for people who do not have partners and do not want children.

Existing NIH policies, programs, or resources

Hire in a postdoc to faculty track so that upon completion of a successful postodc they opportunity to be hired on a faculity exists. Success should be well defined by requirements set forth by the academic institute much like P&T process.

Proven or promising external resources or approaches

Treat postdocs like employees not students. Focus on policies that help retain employees and apply those to postdocs.

Response 2070

Perspectives on the postdoc roles and responsibilities

I think my role is to contribute to the scientific project of the lab, to train students, and to develop an independent research project that will lead me to get an academic position in the near future.

Fundamental issues and challenges

Low salaries, limited benefits (health insurance and retirement), limited number of grants international students can apply to, difficulty getting visas or having to come back to your home country every year to renew it (this means, weeks of absent from work and a lot of money from postdocs), not a clear status in the university (we are not students but neither staff).

Existing NIH policies, programs, or resources

To increase the number of grants international students can apply to, to ask Institutions to hire students as staff, to waranty good benefits such as health insurance and retirement, to have a constant comunication with postdocs in the form of anonymous survey, and to allow postdocs to be recognize by their input while writing grants with advisor such as R01 or R21.

Proven or promising external resources or approaches

More surveys like this, annual evaluations from postdocs to mentors and viceversa, and IDP.

Response 2071

Perspectives on the postdoc roles and responsibilities

opportunity to gain more research experience in a given field or explore a new field while gaining exposure to potential roles in academia or outside of academia. The post doc should have access to a group of mentors to diversity opinions, views, and experiences, but also to have multiple views and exposure to different fields. Additionally, this is the time to learn about the path to independence , however it may look for each post -doc, instead of forcing each post doc to follow the foot steps of the mentor.

Fundamental issues and challenges

Post doctoral fellows at the [redacted for anonymity] are treated like freelance scientists. There is very little mentoring, advise, and career development support. Post docs are used for ideas, to mentor younger scientists, and to finish projects that are close to publication. Few post docs are actually ready to move to tenure track positions and if they do, the support to do so comes mostly from other resources or other mentors not directly involved in post-doctoral training. Moreover, post docs have little to now support when it comes to protection against research integrity violations. That is, the authorship and publishing environment at [redacted for anonymity] does not favor post docs at all. Post docs can work on several projects and be integral parts of completing and publishing a project and still not be included as authors. Meanwhile, time and effort goes wasted. This is on top of the fact that post docs are hired as “Vendors” so many of the policies and procedures that apply to employees, faculty, and staff, do not apply to post docs. Moreover, post docs who are not completely committed to entering tenure track positions are immediately pushed out through the methods previously described (authorship problems), and by creating negative work environments.

Existing NIH policies, programs, or resources

Have a more dedicated center/ institute that supports post doctoral training and that ensures that these individuals are not being taken advantage of. Many of the occurrences at UNM could be stopped if such a department existed--especially for those post docs funded by NIH grants (including training grants).

Proven or promising external resources or approaches

No response

Response 2072

Perspectives on the postdoc roles and responsibilities

I tend to view the postdoctoral position as a unique time in a scientist's career where the individual gets to focus on independent scientific inquiry under the guidance of a mentor. It's a special time in a career between having learned how to think/problem solve during graduate school and having to have extra managerial/administrative duties in future positions. I tell my trainees it's an important apprenticeship of sorts for those who think they want to go on to run research groups either in academia or industry.

Fundamental issues and challenges

When I was a postdoc, the pay level was not sustainable in the long term. Even in a city with a more reasonable cost of living, it was a stretch to afford housing, the overall cost of living, and save money for retirement and other large expenses. I couldn't imagine having to manage the cost of childcare as well, but many postdocs must!

Moving for every stage of my career caused significant strain on my personal relationships and probably contributed to delayed family formation. This may result in me having fewer children than I had hoped for.

We now have to compete with biotech companies with far better compensation and benefits packages.

Many grad students know the prospect of attaining an academic position is slim and are not interested in a postdoc.

It is very difficult to recruit high quality postdocs as a junior faculty member just getting established.

Existing NIH policies, programs, or resources

Better funding for postdocs, or more programs to help early investigators support more permanent research staff.

More opportunities for individuals who are at the senior scientist level to compete for funding. I have a postdoc in my lab that should be moving on to the next stage of his career. Because he had poor mentorship in graduate school, he didn't realize he actually liked academia until the 5th year of his postdoc. I'd love to promote him to a senior scientist and be able to continue to support him in developing his grantsmanship without having to keep him at the postdoc pay level for another 2 years. He really hopes to be a driver of scientific inquiry in the field, but he ultimately may be best served by functioning as a semi-independent senior scientist able to write grant applications and manage projects under the umbrella of another lab, but there is no clear pathway to get there.

More opportunities for postdocs to develop management and grant writing skills.

Proven or promising external resources or approaches

More opportunities for postdocs to develop management and grant writing skills.

Better training for mentors on how to help individuals that want to work in industry.

Response 2073

Perspectives on the postdoc roles and responsibilities

The postdoctoral position is a time for individuals to chart their own course of research while learning from the PI's existing and underway studies. The postdoc's responsibilities are to be well-versed in the content areas and methodologies they want to have an independent research career in. This includes knowing all past and current research in these areas. The postdoc's role is also to be a leader in the lab for staff and other junior trainees (e.g., students). They can help with training opportunities and advice for others (e.g., grad school applications etc). I also believe that it is a time when postdocs should be allowed to run their own small pilot studies, completely in their own area. This means they will formulate the research questions, fill out the IRB, and run the study on their own or under their direction (having help from staff and the PI, of course). This enables them to be empowered, skilled, and capable when they become independent. Without this opportunity, postdocs are unprepared in a faculty position.

Fundamental issues and challenges

Challenges inhibiting recruitment is that there are a lot of great postdoc positions out there. Retention of postdocs may be difficult because some PIs do not allow postdocs to do anything but act as staff in their lab, which makes postdocs find other avenues (sometimes out of academia). Overall quality of life with a postdoc is exceptionally hard. By the time most individuals enter postdoc, they have completed undergrad, masters programs, and doctorate programs, and are in their late 20s or 30s (not all but broadly). They have had to move all over the country for opportunities and probably have just moved to a new place for the postdoc. All of this is done while making incredibly low salaries and heavy, heavy student loan debt. Unless the postdoc is independently wealthy, it is almost impossible to do without taking on more significant debt. Postdocs arrive desperate to do what it takes to finally have a stable job with a stable salary. Programs like the NIH Loan Repayment Program help some but are hard to get. Women in postdocs are under even greater pressure as most are at the age to have children. To figure out the process to give birth, have a paycheck for maternity leave, and still be competitive on the job market is a real issue. It sets women up to be behind in a discipline where we are already struggling to be seen. Postdocs with families or spouses willing to move where the postdoc is have a hard time finding jobs in the same cities. Postdocs are usually with no family, in long distance marriages, or have a spouse looking for a job in the new city (which they will stay at for only a short time; again, setting up for more financial hardship).

Existing NIH policies, programs, or resources

The postdoc salary could be raised and NIH could recognize more outright parental leave policies. I do appreciate the extension of ESI status based on how many children you have. This was an incredibly easy process and one I pass on to others. NIH should expand the NIH Loan Repayment Program to fund more people and create more transparency around scoring.

Proven or promising external resources or approaches

NIH should start to consider how we can help individuals as a whole with work/life balance and how postdocs are individually affected by moving cities because by postdoc, most individuals are no longer college age approaching adulthood. They are full adults with working lives that are drastically changed each year as they work toward a stable and independent job. And, just because those who have been in the field for a long time have had to suffer this same burden, this does not mean we should be putting the next generation of postdocs through it.

Response 2074

Perspectives on the postdoc roles and responsibilities

Postdoctoral researchers are the drivers of scientific innovation and discovery. Free from the responsibilities of a PI, but also more experienced than a grad student, we are in the prime position to drive innovation forwards. I enjoy the freedom in choosing and guiding my own projects, as well as being in charge of my day-to-day experiments and time management, and the creative aspect of science at this level.

Fundamental issues and challenges

First and foremost: Lack of competitive salary/stipend. Almost all of my fellow postdocs and fresh PhDs who have decided against another postdoc cited pay as the number one reason. I myself live in a HCOL area as the sole earner in my family—we effectively live a college student lifestyle while being in our 30ies and having a PhD. My work does not feel appreciated and I am taking a huge pay cut to pursue my dream of being a scientist—but not everyone is willing to do that.

Lack of retirement savings plans and other benefits (maternity support)

Lack of training on new methods/instruments and other skills (team management, writing, presenting, teaching.)

Some groups have very toxic environments (micromanaging, internal pressure and competition, being scooped inside your own group, research misconduct, terrible work/life balance)

Existing NIH policies, programs, or resources

Give postdocs more money

Proven or promising external resources or approaches

Switzerland (NCCR) 120% support grant for postdocs with family responsibility

Response 2075

Perspectives on the postdoc roles and responsibilities

A stepping stone for permanent positions in academia, government, industry, communication, etc. In some instances, personal reasons might limit the person geographically and s/he may opt to continue as a research scientist.

Fundamental issues and challenges

The industry pay scales are not possible to match in academia unless NIH/NSF can provide special supplements. It is also the case that graduate schools are producing far too many PhDs, some of whom are simply not of the caliber expected for postdoctoral positions.

Existing NIH policies, programs, or resources

A fraction of the time should be devoted to broadening skills for her/his future career. Currently, there are no safety nets for such training.

Proven or promising external resources or approaches

Regional symposia of postdocs supported by NIH grants would be a good start. Best practices should be shared and these regional meetings will allow for networking and showcasing of placement opportunities.

Response 2076

Perspectives on the postdoc roles and responsibilities

A postdoc position is an additional training role to bridge gaps in knowledge between graduate work and a full time career. The training can be around new technical areas and should include additional skills such as mentoring, teaching, grant/technical writing, project management, etc.

Fundamental issues and challenges

1. There are not many good academic jobs available, or there is a perceived inability to make meaningful career progress in academia, and so there is a lack of desire to pursue a postdoc to progress down an academic career path
2. If a student wants to pursue an industry position, the skills obtained in a postdoc do not necessarily translate to or are not required for industry positions in specific ways

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 2077

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

The limit on number of external work hours allowed per week places many at a disadvantage. For example, individuals who need the extra income and or members of practice disciplines who need to accrue practice hours to maintain a license or certification, may not be able to devote 100% full time to their post-doc yet practice in real-world settings often complements the academic scholarly work and keeps the post-doc current.

Existing NIH policies, programs, or resources

The pay back agreement limits options for post-doc trainees to work in settings other than academia, yet science is conducted in many settings (industry, practice settings, corporate world, policy, NGOs, non-profits etc).

We need broader criteria for eligibility (immigrants, citizenship status etc) that reflect the composition and diversity of the future workforce

Proven or promising external resources or approaches

We provide trainee opportunities for "practical mentored experiences" in our T32. For these experiences, trainees are embedded in real-world work environments across the field of health technology beyond academia. Trainees choose from among 6 "experiences" (digital health, innovation, commercialization and translation, population health, consumer engagement and health, machine learning lab). These experiences often lead to scholarly products, innovations etc. It would be nice if trainees were paid (since the mentor/sponsor) benefits from the trainee's contributions.

Response 2078

Perspectives on the postdoc roles and responsibilities

I understand why the post-doc position exists. I do somewhat agree that it might be nice to have a training stepping stone role in between grad student and PI. However, I don't think postdoctoral positions should become limbo, where you are in a tenuous positions with tenuous pay for an undetermined amount of time until you can find a "real job." I understand why the role exists and why there is a stepping stone, but I am not willing to do 2 or 3 postdoctoral positions while I apply and apply and apply to faculty positions.

Fundamental issues and challenges

It seems like a miserable job. The expectations seem very high and very high-stakes, PIs can be nasty, the pay is poor, the hours are long, I might have to keep moving cities, total duration needed is unclear, and it seems impossible to achieve upward mobility as a post-doc. It seems industry is always growing and pay is better and compensation level is clear up front. I personally would prefer to stay in academia, but for the simple reason of being able to fund my life/pay off student loans I may not be able to. Additionally, in several cities in the US existing as a minority or woman is potentially unsafe--why would I stay in the US to post-doc?

Existing NIH policies, programs, or resources

INCREASE BASE NIH STIPEND FOR POST-DOCS. I have seen over and over again that universities set their post-doc salary at the baseline NIH level, and use that standard as reason not to increase or go over. A five dollar increase does not compete with inflation. It makes postdoctoral positions very unattractive. I'm not sure how but some sort of way to escape the limbo of being a post-doc for an undetermined amount of time. Consider expanding the NIH loan repayment program outside of biomedical and biobehavioral research.

Proven or promising external resources or approaches

No response

Response 2079

Perspectives on the postdoc roles and responsibilities

To me, a postdoctoral position is an opportunity to become increasingly independent as a researcher. Although this period allows recent graduates to finish up publishing their dissertation work (if applicable), many post docs transition into a new lab with a new mentor. In this new position, post docs become involved in their mentor's work to the extent that it facilitates learning new skills. However, these period should be largely driven by the students needs and goals. The post doctoral period is an important time for recent graduates to accumulate publications and be mentored in writing/obtaining their first grant(s) and preparing for their next step (whether as a faculty or Scientist, etc.).

Fundamental issues and challenges

Because most post docs are relatively short, lasting 1-2 years, a major barrier is relocation. At this stage in their career, many individuals applying for post docs have a long-term partner/spouse and/or family commitments (e.g., children or pets). Relocation is extremely expensive due to moving costs but can also be a huge financial burden if there is a need for the post doc to live apart from their partner/spouse during these 1-2 years. There are also costs from traveling back-and-forth to visit the partner/spouse during the post doc period. There should be the opportunity for remote/hybrid post docs with limited travel every 1-2 months. Otherwise, relocation costs should be covered and assistance should be available to assist with relocating the partner/spouse in identifying a new job (if they are eligible to work in the same facility/institution). Another issue that I have seen among peers, is that nobody wants to accept a post doc position because the pay is significantly less than taking a full faculty position. Several individuals I know are leaving research-intensive institutions for smaller institutions where they can be hired as a faculty and mostly teach. Post doc salaries need to be more competitive to prevent students from continuing to avoid post doc positions. An issue specific to non-citizens/green card holders is restrictions on their eligibility for the T32 mechanism. Many institutions use this mechanism as their primary pathway for post docs, so this is extremely limiting for non-citizens/green card holders when searching for a good post doc match.

Existing NIH policies, programs, or resources

Currently, international PhD students are ineligible for nearly all NIH funding (e.g., F30, F31, F99). This restriction significantly impairs these students' progress towards becoming independent scientists and puts them at a disadvantage compared to their American peers when they transition into post doctoral roles. Non-citizens/green card holders are also ineligible for the T32 mechanism, which significantly complicates the search for a post doctoral position. Further, many faculty and institutions lack awareness that international post docs are ineligible for this mechanism, which leaves PhD students to rely on their peers for guidance on what funding mechanisms they are eligible for as a non-citizen/green card holder. An institution's international student department may be helpful for obtaining some guidance; however, these departments vary widely in their helpfulness and visas and funding opportunities largely vary between institutions. Widespread awareness about existing restrictions for international PhD students/post docs and removal of existing funding barriers for non-citizens/green card holders will benefit students and principal investigators alike when attempting to identify suitable mentor-mentee matches.

Proven or promising external resources or approaches

No response

Response 2080

Perspectives on the postdoc roles and responsibilities

Going into my postdoc fellowship, I expected many responsibilities, with the primary role being research. Now that I'm four years into my position, I look back and realize that my responsibilities have been all over the place. I want to say that research has been my primary responsibility. Still, I'd say it barely takes the lead, and a large chunk of my work is completed by trainees I mentor (I have mentored high school students, undergraduates, graduate students, technicians, and other postdocs directly on my project). Beyond my primary research and mentorship, I also spend a significant amount of time doing administrative work coordinating numerous meetings related to my development as an independent researcher, but also frequently completing progress reports for fellowships and grants my work is supported by, and sometimes completing tasks as menial as coordinating meetings for my, even busier, mentor. After many discussions about my efforts with my mentors, it is clear that they view my efforts as "running my lab within [their] lab." While this is great to hear, and I'm excited about the experience I'll have going into a faculty position search, it only emphasizes my undervalued efforts. Compensation for this position is low, and benefits are minimal (I'm nearing my mid-30s with zero retirement savings). To be at this point with 10+ years of research experience and still be a trainee is disappointing.

Fundamental issues and challenges

I do not doubt that salary is the most important fundamental issue with recruitment, retention, and overall quality of life in academic research. Academic postdocs are underpaid compared to their non-academic counterparts, strongly contributing to a sense of low worth. Further, the demands of postdocs are high; in

addition to research tasks, many postdocs are responsible for obtaining funding, contributing to progress reports, reviewing manuscripts, mentoring, and many more. The list of postdoc responsibilities is similar to the list of responsibilities of a principal investigator, but the pay scale is significantly different. Managing all these work tasks while also trying to establish life as an adult (i.e., buying a house, starting a family, etc.) is challenging with the low salaries of postdocs—other important issues related to this directly, such as retirement. Few programs offer retirement to postdocs and the ones that do rarely contribute or match funds deposited to retirement accounts for postdocs. Quickly, those that pursue postdocs are put behind their counterparts because of a lack of savings for their future retirement. Transparent and equitable maternity and paternity leave are also an issue for current postdocs. While there are many problems that postdocs face, it's evident that the majority of these problems can be summarized as worth, and even more clearly, as the salary is far too low to make postdoc positions appealing to new graduates.

Existing NIH policies, programs, or resources

I think some current policies NIH offers for postdocs are confusing. The F32 is an excellent resource for postdocs to apply to, and I fully support it. However, the K99/R00 fellowship is very complicated. The four-year cutoff is difficult for postdocs working on large complex projects or with slow model systems. Further, expectations vary widely from institute to institute—NIDDK expects high-impact publications, while NIGMS often awards fellowships to trainees with few or no postdoc publications. There is a lack of emphasis on the postdoc-to-research scientist transition, but there is a funding mechanism for research scientist-to-faculty positions (K01). It seems obvious to have a much more structured, higher-paying postdoc limited to the length of F32 fellowships. Trainees that wish to pursue faculty positions should then be able to transition to high-earning jobs in academia (like a research scientist or assistant professor role) and be eligible to apply for K01/K99 like awards or have a good chance to transition out of academia at this point (many postdocs seem to move on at around the two year point). This type of pipeline is more similar to traditional career paths that offer room for growth within and beyond the current position instead of lumping many trainees into a single postdoctoral category.

Proven or promising external resources or approaches

No response

Response 2081

Perspectives on the postdoc roles and responsibilities

Not everyone wants to become a prof. Postdocs are becoming increasingly seen as mainly for people who want to stay in academia on a tenure track course. For postdoc positions to be viable there needs to be greater opportunities for career development etc for non"traditional" routes

Fundamental issues and challenges

Most R1 institutions are in major cities with high cost of living. This makes it hard for faculty to attract candidates since industry postdocs pay twice as much for half the work. For example at my institution the rate was just raised to 65K. Median income in the city is 76K, and realistically in the neighborhood that the university is the median income is probably closer to 100k. Paying people with PhDs 65K makes no sense when I could have a bachelor's degree, go to industry, and make at least 70 to 80K. PIs also need more support from the NIH as institutions raise salary minimums but the NIH rates stay the same. What does essentially means is that especially for younger PIs they have to have multiple grants for each postdoc that they want to hire

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

Response 2082

Perspectives on the postdoc roles and responsibilities

My understanding of the postdoc position was/is that it is a training role designed to foster independence and provide additional training in a new skill set for that individual to eventually start a research program of their own at an academic institution or industry. Postdocs are also a training opportunity if you need to gain an additional skill or experience for an industry job that you did not have access to during your graduate training. Because universities and the NIH do not view postdocs as full-time employees, or categorize them differently due to their "trainee" status, I do not view post-doc positions, nor do I think they should be viewed as, a primary source of labor in a lab environment.

Fundamental issues and challenges

There are not enough principal investigator positions opening up to support the number of postdocs currently in training. I think what most labs need, and what many current and past post docs would want, is to hire full time, highly trained staffed, which is what postdocs are. However, postdoc pay and benefits (if any are even offered) comes no where close to what the expertise of that postdoc is worth, and therefor many are going elsewhere. I recently transitioned (within last 4 months) to an industry position. I enjoyed my postdoc but I did not want to be a PI in the current university system. I would have gladly stayed in my postdoc lab as a staff scientist if that were an option, and the University valued me as a full-time employee that provided better salary and benefits. It would have been even nicer if I could have received a bump in salary commensurate with my years at that institution.

Existing NIH policies, programs, or resources

I think the NIH and Universities need to consider that graduate student and postdoc "trainees" are not there to primarily be trained but to provide labor for science. This is not bad, many people obtain a PhD and continue to a postdoc because they enjoy doing science labor over other labor types, but they need to be paid and valued more as laborers, especially postdocs who have a terminal degree, and not cheated out of benefits under the guise of "trainee." There is no "certificate" or additional degree you get from a postdoc except experience, and that comes with spending additional time in ANY job. Even phrasing these questions with "postdoctoral training ecosystem" and referring to postdocs as trainees undercuts the serious accomplishments people must have received to hold a postdoc position. I think the number of "post doc" positions should be cut and instead replaced with staff scientist designations so Universities cannot hide behind "trainee" and withhold benefits due to individuals holding a terminal degree with many years experience in their field. Staff scientist positions could be graded by experience post-PhD (Junior, Senior, etc) providing a title that also reflects someone's experience. It is just not economically viable to continue in a position that does not guarantee a basic retirement fund/plan, has sub-par health insurance in a lot of cases, and also pays terribly despite that position providing a SIGNIFICANT amount of the labor necessary to generate data for grants, publications, and IP for new tech and drugs.

Proven or promising external resources or approaches

I would look to the medical training field. I am partnered to someone currently in residency and there is A LOT wrong with medical training as well. But their pay is better, increases more dramatically with years experience post MD, and they are considered employees at the hospitals in which they work. Some also receive retirement plans with match, which I have never seen offered to a post-doc. These programs, so I've heard, are also incentivized or prefer to retain many of the residents they recruit. In medical training, you are not significantly hurt by staying at the same institution. The culture that you MUST move institutions during your academic training imparts further economic and social hardships on academics already paid poorly.

Response 2083

Perspectives on the postdoc roles and responsibilities

In my view, a postdoc should be able to drive the lab to the next level and at the same time, it is the responsibility of the mentor to build the postdoc into an independent researcher. This can be achieved by allowing the postdoc to write an independent grant and provide funding for procuring basic research stuff for generating preliminary data for the grant. A mutual understanding and dependent growth of mentor and trainee should be there. However, even if the mentor wants to support the postdoc, challenges occur

when it comes to funding. The biggest challenge for the postdoc is the basic stipend. After having a highly qualified degree, all the postdocs across the countries are underpaid. This drags the postdoc to move into industries and make them work as a robot, which is not good.

Fundamental issues and challenges

The big challenge definitely the uncertainty. This could be due to visa issues (if international), funding issues and underpaid salary.

Existing NIH policies, programs, or resources

We appreciate the NIH for taking initiative for this kind of invaluable survey. Definitely, the first thing need to modify is the salary. A minimum $75,000 pay scale is required for the postdocs with yearly increments. More grant opportunities are required for both national and international postdocs.

Proven or promising external resources or approaches

No response

Response 2084

Perspectives on the postdoc roles and responsibilities

Preparation for a principal investigator position

Fundamental issues and challenges

Low salary, stressful environment and short contract (One year is too short). A postdoc should be at least two years.

Existing NIH policies, programs, or resources

Encourage or obligate PIs to provide better conditions to their postdocs. Those conditions include : good salary, assistance in case of difficulties, two years of contract without conditions but renewable or not based on the performance, holidays and others.

Proven or promising external resources or approaches

Postdocs should evaluate their PI and future grants should be denied to bad PIs who mistreats their postdocs

Response 2085

Perspectives on the postdoc roles and responsibilities

Academic postdoc is a employee with a training component for the next job. I expect the following from the postdocs

1. Coming to work on time and showing up everyday.
2. Execute research independently with less supervision that a graduate student
3. Write postdoctoral fellowships
4. Help in grant writing
5. Share their expertise from Ph.D. with the lab
6. Train Ph.D. students and undergraduate students

Fundamental issues and challenges

1. Quality well trained postdocs have disappeared
2. As many postdocs got their Ph.D. without publications, they are not well trained.
3. Future pipeline of what they will do after postdoc training is not clear
4. Conversion of postdoc to academic job position is not efficient. Hence important to train postdoc with open minded approach and giving them job options
5. Postdoc positions should be maximum 3 years so that they are aware it is a training and employment but not a permanent job.
6. Postdoc salaries has to be adjusted using cost of living calculator and not just keep increasing.
7. NIH modular budget needs to increase to at least 300K. Everything has become expensive and this budget has not changed.

Existing NIH policies, programs, or resources

1. Increase NIH modular budget to 350K
2. Make sure that postdoc salary is calculated using cost of living calculator. Maybe schools in California should give housing allowance.
3. Increase postdoc perks: healthcare, housing, campus housing access, travel allowance etc.
4. Pay postdocs 2K per year for travel

Proven or promising external resources or approaches

There could be centralized recruitment for postdocs where nationwide everyone with NIH funding can advertise

Response 2086

Perspectives on the postdoc roles and responsibilities

Currently, academic postdocs are expected to take leadership/ownership of at least one scientific research project, giving input into how the experiments should be run, troubleshooting, writing manuscripts, fellowship applications, grants, etc. However, it is also supposed to be "additional training" after earning a PhD, with the PI giving professional development/career advice. However, the majority of the postdocs I have interacted with and met do not feel like their postdoc positions even touch on this important aspect of "postdoc training". Postdocs are "essential" for academic research, but only because they have been severely underpaid and underappreciated. They produce the majority of data in these labs, and the system will fail without them. They need to be treated with more dignity and respect.

Fundamental issues and challenges

Postdocs already have a PhD; they have the necessary background and training to get the science done. Yet, the pay they receive is pennies compared to what they could be making in other industries. That and PIs are essentially running postdocs ragged with how much they expect of them, with most having little to no work life balance. Why would PhD graduates, who have already given 5-6 years of their life working so hard for not nearly enough compensation, want to go into a postdoc when they know they'll have to work even harder for not much more? PIs treat postdocs like a glorified tech, in the fact that they do not give them additional career or professional development training, WHICH IS SUPPOSED TO BE THE POINT OF A POSTDOC.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

Make PIs accountable for giving postdocs the necessary career/professional development training—maybe set up a way for postdocs to indicate to the NIH if these aspects are not being covered in their training, or if they are feeling taken advantage of. Have NIH take these into account when awarding grants, as to not

reward PIs who are not properly training/respecting their postdocs. Ensure reasonable working conditions/hours. Increase minimum postdoc salary.

Response 2087

perspectives on the postdoc roles and responsibilities

A postdoctoral position is a training position that is supposed to train PhD holders for their careers. It should allow career development and CV building. The postdoc should have a mentor that keeps in mind the goals and future plans of their postdoc mentee and work on helping the postdoc achieve them. The postdoc should in turn endorse the assigned responsibilities that would be mutually beneficial to both, the postdoc and the mentor.

Fundamental issues and challenges

After graduating with a PhD, graduates have the option of getting a real job with high pay or doing a postdoc with less pay. The main reason many postdocs choose to do a postdoc is for the training and CV building. They aim to fill the gaps in their CVs and become more competitive for future better jobs, specifically academic ones. That is why they sacrifice the extra pay. However, unfortunately, their aims are rarely fulfilled during the postdoc years.

The main challenge is the autonomy of the postdoc. Most postdocs are funded by their PIs' grants and therefore postdocs are always under the mercy of their PIs. They feel coerced to do everything they are asked to do with almost no protection or support. Postdocs end up serving as technicians with almost no CV building.

In addition, postdocs have minimal benefits and very low pay.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

Research has continuously proved that employees who are offered autonomy, the chance to grow and better benefits are always more productive.

Response 2088

Perspectives on the postdoc roles and responsibilities

I view the postdoc position as an opportunity to gain additional training in new techniques, systems of study and also as a time for professional growth as a scientist. This is a valuable opportunity to further develop ones skills in leadership, project management, mentoring, and manuscript and grant writing. It should, in my opinion, be a time of increasing independence from the mentor and should be structured around the intended goals of the trainee.

Fundamental issues and challenges

Financial: relocation costs, childcare costs, housing in high cost-of-living areas.

Uncertainty for advancement: one of the challenges facing postdocs today is that with competitive jobs in academia the expectations to obtain a TT position have drastically ballooned. As a consequence trainees are spending longer periods of time as postdocs as they wait to jump to independent positions. A priori this isn't a problem if postdocs are well compensated in ways that would allow them to support themselves and their families.

In some cases there is a sentiment that biomedical research is dependent on a low-wage trainee workforce, both graduate students and postdocs. This results in some faculty using postdoc hiring to accomplish jobs that may otherwise be well served by a staff scientist.

Existing NIH policies, programs, or resources

Limit ability for PIs to pay trainees from research grants. Instead, expand training grant opportunities and move to a system where graduate students and postdocs are linked to fellowships. Fellowships should be dispersed in ways that university benefits are retained by postdocs. Scale postdoc salaries by cost of living

index. These actions would prevent PIs in high cost of living areas from being double jeopardized by difficulties in recruiting and having to raise more grant support to cover the minimum postdoc salaries being mandated by an increasing number of institutions. This would ensure research support is (largely) being used for research costs, and personnel costs are shifted to other funding lines that provide postdocs with adequate financial support to allow them to focus their attention on research. I suspect this would increase diversity within the postdoc pool (women, minorities and those from low-income backgrounds) would not feel squeezed between following their passions and financial pressures they may have. Further, it would allow scientists from non-traditional paths who might be older and have these additional family expenses to remain. Expand staff scientist positions. Stable salary lines for PIs would be transformative in many labs, and by allowing for stable tech/lab manager/staff roles to be maintained this would free up the capacity of postdocs to truly be training experiences.

Proven or promising external resources or approaches

No response

Response 2089

perspectives on the postdoc roles and responsibilities

The postdoctoral experience (in a research context) is a time dedicated to obtaining any specialized training, hone skills, learn new skills, and building one's research portfolio following one's graduation of an advanced degree (i.e., doctoral or equivalent). Often, because manuscripts are one of the main forms of currency in academia, a postdoctoral fellow will use this time to publish papers and increase their number of publications. Postdoctoral training is also a time for professional identity development and can serve as a transitioning point from trainee to a junior colleague/independence. Yes, technically a postdoctoral position is still a training position, but having completed a minimum of 5 years of training at the graduate-level, postdocs are a unique, more advanced type of "trainee."

Fundamental issues and challenges

Financial challenges are among the top reasons for reduced recruitment and retention as well as poor quality of life in academia. I know many colleagues who have left their postdoctoral position to pursue industry/non-academic research roles in order to earn a living wage. To put this into context, here is a personal example that likely reflects the experience of many, but not all, postdocs: I am a first-generation student (college, master's, and doctorate) who made ~$15k/year during graduate school and has student loans. I am in my early 30s and am unable to prepare for my future (e.g., save for retirement) because I am underpaid and trying to make ends meet on my postdoc salary despite the significant amount of training I have had. I am constantly worried about money, paying bills, repaying loans, my future, and so on which significantly reduces quality of life. Because of the T32 funding mechanism, I am not eligible for retirement benefits at my institution and have to put my life on hold, yet again, to have a chance at being an academic researcher. It is not feasible and it is not sustainable, especially for people from disadvantaged backgrounds (like myself, as per NIH's definitions).

This will vary by setting, but it also feels like you have to continue to put your life on hold, which reduces quality of life and does not model healthy work-life balance. Although I do not have any concrete ways to improve this given the variability, it would likely benefit NIH to take this into account.

Existing NIH policies, programs, or resources

Reconsider stipend structure and allotment: Going into the next FY, as a postdoc w/3 years of experience I will make less than a postdoc w/0 years of experience because my money is allotted from the year prior though my appointment will occur in FY2023. Essentially, I was pressured into starting postdoc on 6/30 so the PI would not lose funding, even though they had funding for the next FY. There must be a better way to do this and improve equity. Potential postdocs should not feel forced to start earlier (on paper) to help the PI. Current postdocs should not be punished because of the national postdoc recruitment and retention crisis.

Other financial/stipend concerns: It is unrealistic to think a one-size-fits-all stipend is equivalent across the country. I declined my top postdoctoral fellowship (one of the nation's top programs in my field) because living in that state on the NIH stipend would result in further debt. Existing policies prohibit postdocs who receive an NIH stipend to receive retirement benefits. Postdocs also get slammed with

thousands of dollars at the end of the year, with no formal guidance, and in some cases warnings, on paying taxes throughout the year to avoid tax penalizations.

Payback obligation: Is there another way to achieve what NIH is trying to with the payback agreement? Honestly, it can be seen as manipulative because if someone takes a position and it is ends up that it does not work out/is no longer in the person's best interest, they are essentially stuck in this position or a similar one because if they decide this is not for them, they have to pay back the stipend. As people seeking postdoctoral positions, this is something I have heard is a "turn off," steering people away from these positions.

Proven or promising external resources or approaches

Ã…lund, M., Emery, N., Jarrett, B.J.M. et al. Academic ecosystems must evolve to support a sustainable postdoc workforce. Nat Ecol Evol 4, 777-781 (2020). https://doi.org/10.1038/s41559-020-1178-6

Response 2090

Perspectives on the postdoc roles and responsibilities

I believe it is a training position designed to develop research independence, establish a research output trajectory that can be carried into an academic research faculty position, and impart the skills needed to determine the significant biomedical problems that need focused investigation.

Fundamental issues and challenges

Many postdoctoral mentors use their trainees as a less expensive workforce for their own research grants rather than providing the infrastructure in which the trainees develop their own independent ideas. The trainee then has to negotiate what can be considered their own as they move to the next career stage. Although the NIH postdoctoral trainee stipend has out paced inflation over the past 32 years, it still lags what an individual could earn in the for-profit sector. That coupled with the long hours of work required by most postdoctoral mentors, contributes to a lower quality of life feeling.

Existing NIH policies, programs, or resources

The length of time for a postdoctoral position should be 4 years with the first 6 months devoted to training and learning new concepts and techniques and the last 3.5 years devoted to independent research where the trainee owns the IP. This has the advantage of entering an already established research infrastructure so time and dollars are not needed for that set up and it provides a clear road to research independence. The NIH should enhance the number of K99/R00 awards and expand the K99 portion to 4 years that includes a research supply budget and ensuring the R00 portion has at least 8 modules of direct costs per year. This could in part be funded by reducing the number of F32 awards as they are simply budget relief for the postdoctoral mentor and do little to promote a trajectory of true research independence.

Proven or promising external resources or approaches

The Big Ten Academic Alliance postdoctoral advancement initiative, which was initially NSF-funded, provided valuable postdoctoral networking and professional development that linked participants with potential hiring institutions and departments. Expanding programs that maximize the fit for a postdoc trainee as a potential faculty member allow that trainee to see a clear pathway to an academic research career.

Response 2091

Perspectives on the postdoc roles and responsibilities

A postdoc is a lot like doing a second PhD project, except if it doesn't work out you can leave without having needlessly wasted your time.

Fundamental issues and challenges

Because a postdoc is fundamentally still a training position making it difficult when looking to establish some sort of permanent, stable lifestyle. Not to mention the ever-present possibility that your PI could move and with it your job and project. Postdocs have already spent a number of years in these temporary positions during their PhD and oftentimes other tech jobs or masters programs between undergraduate

and PhD programs. This means that between completing the PhD program and a full postdoctoral project, more than 10 years could have passed between completing the undergraduate degree and postdoc. This is a long time to before obtaining your first "real" job. During this time people who went to work right after undergrad have been able to buy houses, start investing in their retirement plan, and move up the corporate ladder. Between the time spent as a graduate student and a postdoc, there are usually little to no savings for retirement and if you've been on fellowships for a significant portion of that time you may not even be vested in social security. Furthermore, with the nature of these jobs being more like a running a small business—you only get the payout of a manuscript when you complete the project—it heavily discourages taking time off for vacation as that will only prolong the training period. And for all of this work, it is usually known to be unlikely that your institution will allow you to move on to a more permanent position. Unless trying to move to an academic position, there is little reason to spend much time in doing a postdoc because one could likely move up the corporate ladder faster by starting their job rather than publishing a better paper.

Existing NIH policies, programs, or resources

Response 2092

Perspectives on the postdoc roles and responsibilities

The academic post-doc should be a time for individuals to receive additional specialized training to advance their research. The post-doc is a unique position that is both a learner and an employee of the individual lab conducting the work. The post-doc should be focused on learning a new skillset. They should have time for learning, mentorship, and writing. The aim should be a clear new skill—in addition to what they learned in their graduate training.

Fundamental issues and challenges

Postdoctoral positions have become a stepping stone for Tenure-Track jobs. I do not believe this should be the case. They should exists, but they should only be used for individuals who need additional specific training. A major challenge in recruiting postdocs is many want to continue on what they were doing prior and are not interested in learning new skillsets. Another challenge is that since many post-docs are for one or two years, by the time they are set up int he lab or research space they are already leaving—resulting in little being accomplished. The NIH Salary amount keeps wages low and does not account for cost of living in many areas. In addition, the fees associated with many universities in hiring a post-doc prevent the scholar from getting them to be engaged in the work. By the time they are settled they are already looking for the next postdoc or opportunity.

Existing NIH policies, programs, or resources

We should raise the available salary of post-docs. We should limit people to one NIH funded post-doc. Post-docs should be limited to the first four to five years after their grant. Post-docs should be encouraged to apply for K awards.

Proven or promising external resources or approaches

Postdocs should be available but not a requirement as part of the academic life-cycle.

Response 2093

Perspectives on the postdoc roles and responsibilities

From the perspective of the trainee, an academic postdoc should be a springboard to a successful future career as an independent and productive scholar.

From the perspective of public health, the role and responsibility of the postdoc is to train efficiently and Move On Quickly to their new institutions where they are independent faculty, and where they will bring their unique blend of training perspectives (unique to their training history).

It has been shown repeatedly that the individuals who up-end their field and change it forever for the better are almost always early career scientists who were bold enough to risk their careers to apply their unique vision to long-standing problems in the field. Currently, it is nearly impossible for early career scientist-trainees to do much other than frantically search for funding while carrying out a senior PI's research aims.

The NIH and the public health will never receive the most field—and world-changing ideas unless they create greater opportunities and more supportive environments for early career scientists, including postdocs. The largest and absolutely most dire and pressing needs are much higher salary and greater protection from exploitative and/or abusive PIs.

Fundamental issues and challenges

It needs to be emphasized that postdocs, and especially those such as myself from disadvantaged backgrounds, arrive to institutions having spent a very long time riding a financial knife-edge, hoping to avoid a major illness or accident, or other misfortune that can easily derail a career and ruin one's financial life. Being a postdoc means having a willingness to gamble one's luck for a few more years, while just staying afloat on debt payments. Understandably, fewer and fewer individuals are choosing this career path. It seems to entail an additional 3-6 year gamble while being insufficiently paid and not infrequently abused and exploited.

Under the current system, the role and responsibilities of a postdoc are: to be a temporary worker, hired to carry out the Specific Aims of a senior investigator. As an under-represented minority from a disadvantaged background and an advanced postdoc, I have found it heartbreaking to have to consider abandoning an academic research career that I spent the last 10-12 years building, simply because I cannot afford it for much longer.

Existing NIH policies, programs, or resources

Response 2094

Perspectives on the postdoc roles and responsibilities

An amazing time in my scientific development. Accepted as a scientist, respected as a scientist, with freedom to explore. Pay was pitiful, but I survived.

Fundamental issues and challenges

Grant support for PIs so very difficult to maintain, leading to anxiety and loss of intellectual curiosity.

Existing NIH policies, programs, or resources

No thoughts here.

Proven or promising external resources or approaches

This is a systemic issue, not just at the post-doc level. Academic life is so different now than when I was a post-doc. Not much about it is viewed as worth the massive effort it takes to succeed, and I don't mean doing bench work, I mean gaining funds to do so.

Response 2095

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

The number one issue without question is the current stipend. Its incredibly hard to recruit doctoral level scientists, asking them to relocate (no funds to cover this), guarantee only 2 years of funding (little to no opportunities for career development), for a pay that is so incredibly low.

Existing NIH policies, programs, or resources

Restrictions on applications for career development grants, where a postdoc cant apply unless they have a faculty position, make it impossible for postdocs to develop their own grant proposals and advance in their careers. The K99/R00 only effectively works if a doctoral students starts formulating a proposal within their last year of their doctoral phase so that they can receive the award within their first year of a postdoc. Realistically, most doctoral students need to focus on their dissertation and not on a future career award. In addition, for epidemiologists, behavioral scientists and other non bench scientists a K99/R00 translates into a 3-4 year postdoctoral fellowship, even if they apply within the first year of the postdoc, which is not the standard and frankly considered unnecessary in those fields. Thus if the K99 mechanisms is the only path to developing a career development award for a postdoc its counter productive to a vast number of doctoral level scientists.

Proven or promising external resources or approaches

RWJF had a program called New connections where postdoctoral fellows and early career faculty could apply for funds to conduct secondary data analyses research. The awards were small, similar to an R03, but the ability to write a grant proposal and receive a small amount of funds to partially cover the salary provided a much needed experience. The program also had a huge component on mentoring and networking. A program like this but only for postdoctoral fellows (if open to early career faculty postdocs it would become to competitive and postdocs would loose out to others with more experience) would be a great program to add as small career development award.

Response 2096

Perspectives on the postdoc roles and responsibilities

It is difficult to determine as some instances you are considered an employee and gain employee benefits but other instances you are a "fellow" or "Scholar" and you have less benefits and less pay. This is difficult to reconcile with in the job market and makes industry seem like a more livable option even if I wanted to continue on the academic route. The only other option is if I already have a partner who makes a livable wage or has good benefits.

Fundamental issues and challenges

The first one is the actual salary. Most institutions say they are limited to the amount that is set by the NIH which doesn't change with cost of living in a particular city or state. The other is that benefits are variable based on your funding and even cost which beg for more income to cover this cost If it is not covered by the PI. Lastly, there should also be relocation assistance offered. usually grants provide funding for travel but it is very rare for a Postdoc to travel in that first year as they are writing their own grants and collecting data and getting settled. So maybe that first year of support could include relocation funding or reimbursement to assist in the cost of moving. This would help especially with most postdocs coming with a family or dependents. Additionally, there needs to be more focus on diversity-related fellowships and grants. There isn't a full pipeline for most centers like NCI for Diversity F99/K00 or Diversity K99/R00 or other awards. There are K01 but that makes you ineligible for the transition awards.

Existing NIH policies, programs, or resources

There needs to be more training in what being a PI means. Yes, we get a ton of training to be great independent scientists, but running a lab is a lot like running a business. You have to know how to find the right people, you need to learn how to budget for a lab regarding reagents, animals, people, publishing, conference travel, etc. Lastly, you need to know how to navigate study sections, reviews, protocols, IRBs, IACUC requirements, MTAs, and other needs for the business of science.

Proven or promising external resources or approaches

No response

Response 2097

Perspectives on the postdoc roles and responsibilities

I view it as a way to perform cutting edge research that advances my academic career, with the hope that this will result in a permanent (tenure-track) academic position.

Fundamental issues and challenges

The pay is abysmal considering my training and skills. The academic job prospects on the other side seem scarce.

Existing NIH policies, programs, or resources

Higher salaries (>= $100,000/year) are by far the most important thing; this is closely followed by more certainty with respect to jobs (especially concerning location). The life stage of a postdoc is the one where we are hoping to start families—the inadequate pay coupled with the uncertainty makes this seem impossible.

Proven or promising external resources or approaches

Competitive pay.

Response 2098

Perspectives on the postdoc roles and responsibilities

The postdoc position is becoming more and more outdated as faculty jobs dry up and people are pivoting to industry and other alt-ac careers for better pay and quality of life. I do not think there is any effective way to remedy the current postdoc system, it needs to be torn down and rebuilt. I truly doubt that superficial remedies such as expanding access to fellowship opportunities, increasing pay and benefits, and providing better professional development will be enough to stop the trend of Ph.D.s choosing not to do postdocs. Rather, postdoc positions need to become actual, well paid, training for tenure track faculty positions (whether in teaching or research), with a guarantee that a job will be waiting for them at the end of it—more like a medical residency. This would entail treating postdocs more like assistant professors or independent fellows—inviting them to faculty meetings, ensuring they are intimately involved in applying for grants, giving them students to mentor etc.

Fundamental issues and challenges

It is fairly easy to fall into a postdoc position after finishing your Ph.D., but it is often not the most strategic career choice. According to a 2020 Nature survey of postdocs (the publication's first survey of postdocs EVER), 63% of postdocs reported that they were planning to pursue a career in academia and another 26% were unsure. However, results from another postdoc survey published in eLife in 2018 indicated that only 15% of postdocs actually end up in these coveted tenure track positions. This means that there are thousands of talented researchers that will be left in the unfortunate position of jumping from postdoc position to postdoc position, becoming poorly paid and under-appreciated adjunct faculty, or having to pivot to an alternative career path that their years of academic training didn't directly prepare them for.

And requiring a postdoc for tenure track positions (which is the case in many STEM fields) certainly contributes to the lack of diversity in the upper echelons of academia. Not everyone can move to a different institution for a temporary position that pays around $50K/year (the minimum set by NIH and NASEM) after making even less in grad school, especially when it's not a guarantee that it will lead to a permanent faculty position. Postdocs with children, postdocs who are disabled or chronically ill, postdocs who are caretakers, postdocs who don't have financial safety nets via parents or spouses, are all at a disadvantage. It should also be mentioned that ~50% of postdocs (according to the eLife survey) are not citizens or permanent residents, which is a situation that can lead to even more precarity and potential abuse.

Existing NIH policies, programs, or resources

NIH could require that in order to receive a T32, institutions must commit to creating faculty positions, or other permanent (and well paid) research or teaching positions, to offer postdocs in the program at the end of their training.

Proven or promising external resources or approaches

No response

Response 2099

Perspectives on the postdoc roles and responsibilities

Post-doctoral positions are full time research jobs where there is an element of training and a clear deadline to the end of this training. Ie after 6 years of postdoctoral training, the postdoc has to be hired as a staff scientist if staying in the same lab

All postdocs should have their own project and if they wish, have another project that could help them achieve scientific independence.

Postdocs should also train students, teach classes and be active in department/institutional activities and be given credit for such efforts through fellowships and awards

Fundamental issues and challenges

No response

Existing NIH policies, programs, or resources

Increase the base salary of postdocs to at least 70K (not including insurance) and make retirement planning like 401K mandatory. This is lower than industry position to acknowledge that the postdoc position has an element of training, but also recognizes that this is skilled labor that should be properly compensated

Limit the number of years to postdoc and increase staff scientist positions

Proven or promising external resources or approaches

HHMI postdoctoral fellowships at Janelia campus

Response 2100

Perspectives on the postdoc roles and responsibilities

I feel as if though postdocs are trainees they are still treated the same as students. They have earned their degree and should be treated as a colleague.

Fundamental issues and challenges

Pay and lack of benefits.

Existing NIH policies, programs, or resources

I think that all institutions should be required to provide benefits such as medical, dental, life insurance, and retirement packages. The minimum pay is outlined but benefits are not.

Proven or promising external resources or approaches

There should be polls sent to every postdoc and postdoc society.

Response 2101

Perspectives on the postdoc roles and responsibilities

The postdoctoral position is defined everywhere as a temporary trainee position that is supposed to train you for leading research and research groups (as opposed to a Ph.D. where one learns to DO research). It is a time when one is supposed to develop a vision and a research question to which they will dedicate their early career efforts.

Fundamental issues and challenges

Simply put, NIH-funded postdoc research positions in the US are an excuse to bring in cheap foreign labor in restrictive conditions. Postdocs “enjoy” less academic freedom than in their foreign former Ph.D. training, and are expected to stick to their benches and desks rather than developing their own vision. The management training aspect is minute to nonexistent and the focus is on conducting research rather than running it. A few workshops per year are given as lip service by the university for research management and job search, but no aspect of that is present in the day-to-day. In their fifth year postdocs are still

considered a trainee even though most will already have ten years or more in conducting research. The training is used as an excuse for lower salaries despite the extensive experience or the costume of many PIs to pull their hands off the leadership training aspect.

The postdoc life is a combination of restrictive visa policies in changing workplaces (University needs to approve visa transfer), low cost to the academic employers, the lack of job laterality, and the academic clock from Ph.D. This should be added together with the requirement for previous employer recommendation letters and the desire to avoid moving one's family shortly after relocation to the US. All of these create fertile soil for a toxic work environment (with around 50% of postdocs and Ph.D suffering from mental issues) and lack of PI commitment. This is to the extent that universities hold at hand the wage, visa, and sometimes even housing at the same time.

Existing NIH policies, programs, or resources

1. Postdocs should not be considered trainees but rather trained time-limited full employees.
2. Salary should be doubled at the expense of the total number of positions offered, comparing it to the level of Ph.D. holding employees in the open market (with adjustment according to location).
3. PIs and institutions should be measured by the results of their postdoc training (publications, and outcomes such as the number of tenure track awardees and penalized for duration) scored and future grants should be dependent on the results. detailed results should be available in an open database.
4. J1 Visa should be abolished and a time-limited free employer visa should be granted for postdocs allowing more freedom to deal with abusive employers, therefore, creating pressure on PIs to perform in the training aspect.
5. Grants and awards should not have Ph.D clock (Ageism), and more project-oriented (rather than personal) grants should be open to foreign postdocs.
6. NIH should encourage creating lateral structure in academic research dismantling the current "up or out" structure and allowing experienced researchers to be involved in academic research without discrimination regarding grant opportunities (see 5) creating a structure more similar to other non-profit institutions and companies.

Proven or promising external resources or approaches

Performance reviews (also for PIs), Open data regarding postdoc and post-postdoc employment market. Higher salaries attract more applicants. inspection and auditing of PIs mentoring and training outcomes and creating a dependency between grants and results.

Response 2102

Perspectives on the postdoc roles and responsibilities

Many PIs are occupied with numerous tasks outside of the laboratory/their research, and this is favored in academia. They have little time to take care of their groups or read and think about the projects etc. Their research and groups are mainly dependent on the fitness and intellect of postdocs and these labs are de facto run by postdocs. The development of the personal career of these postdocs is hindered on purpose so that the PI/academia can use their energy and intellect as long as possible without paying the adequately and giving them rights (e.g. to apply for grants) adequate to their responsibilities.

This is a structural problem where the main burden of science/research is put on the arms of underpaid postdocs. It is good that these postdocs leave the research because academia should be run by full-paid faculty and not underpaid postdocs. However, of course, the problem is that a lot of talented young people who have a huge intellectual potential to move research forward will leave academia. Especially dangerous is that being postdoc and staying in academia starts to be a synonym for a loser: underpaid, someone who lets being taken advantage of for years, someone who lets being.

Therefore:

- it should be accepted that the majority of PhDs leave academia without ever being a postdoc
- NIH should support a structural change back to fewer (trainee-level paid) postdocs and more (full-paid) faculty positions
- Postdoc should be pre-tenue with around 50% transition to faculty within 3-4 years
- Academia/research should be run (majority of intellectual/academic work done) by employed people with an adequate salary, and right to develop their ideas=apply for grants and not by 35-40 years old "trainees"

Fundamental issues and challenges

The fundamental issue is how little post-doc is being paid. Obviously there are other issues like being overworked, being undervalued, toxic power dynamic but those are not issues only in academia. The fundamental issue is the pay!

Just because postdoc is still training does not mean that postdocs should earn less because they are learning something. Almost every job is associated with learning/training for the next step in the career ladder. Postdocs are highly-educated and highly skilled people that deserve to be paid for their value and work. It's a job. What postdoc is being paid now is barely enough to afford a living with the inflation rate and in the coastal area, the postdoc stipend is straight up not enough to cover basic rent. We are in our 30s, with no savings (some still need to pay off student loan), and barely able to afford a living alone (let alone for having a family or children). The problem is the pay. Industry is paying 3x more for PhDs fresh out of grad school and you wonder why people walk away from academia. Yes it's not all about money and we love doing science but if we cannot survive on the current stipend, then yes the issue is the money.

Existing NIH policies, programs, or resources

Response 2104

Perspectives on the postdoc roles and responsibilities

I view a postdoc position as the chance to reinvent yourself as a professional scientist under new guidance. As a fully trained, troubleshooting scientist I am responsible for driving my own research forward, with more general and broad guidance from a PI. At the same time, I explore the area of research and try to generate a plan to establish my own independent research program.

Fundamental issues and challenges

Pay is extremely low. I have several colleagues and friends that went into various industry, consulting, or government jobs that are making 2-4 times what I make as a postdoc. Sure, they have less freedom to

follow their own interests, but PhDs are curious by nature and don't shy away from learning. Because of the low pay, things like a mortgage, child care, life events, car accidents, child birth are all scary.

The incentives for gaining individual funding are broken. At my institution, postdocs receive benefits as an employee, including healthcare and retirement. If I were to be awarded an F32, I would lose both benefits and classification as an employee. While my salary would not change per NIH guidelines, my institution would no longer pay me as a employee. So, by achieving a major goal, to receive NIH funding, I would be punished by my institution, losing ~$10,000 in benefits per year. I would be required to pay for my own healthcare out of pocket from the salary that has not changed.

Great as is.

Fundamental issues and challenges

None. Great as is.

Existing NIH policies, programs, or resources

Provide a platform to discuss multi-generational challenges. Ex, differences in personal/professional viewpoints between early and late millennials, vs baby boomers, Gen Z, etc.

Proven or promising external resources or approaches

Create a platform that trainees are required to meet in institution-based focus groups with other trainee-colleagues in other disciplines. Ex, engineering post docs are required to participiate in a focus group with nursing, or veterinary sciences, etc.

Response 2107

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

Salary Issues and Solutions

1. Postdoc salaries increase as work experience accumulates; however, only post-PhD experience is counted. Some postdocs have full-time work experience in the field prior to completing a PhD. For example, I was the Vaccine Adverse Events Reporting System (VAERS) Coordinator for the entire state of [redacted for anonymity] for 2 years and a study coordinator on an NIH-funded R01 randomized trial for 3 years. However, that experience does not bump me up on the NRSA stipend payscale. Allowing previous experience to count (even if 2 years of experience pre-PhD work is counted as equivalent to 1 year of post-PhD work) would recognize the considerable expertise and professionalism that postdocs bring to a position.
2. I was offered three T32 postdoc positions. They all paid about the same stipend level; however, the cost of living in each location was vastly different. Stipend levels should adjust for location.

Existing NIH policies, programs, or resources

I chose a T32 postdoc position instead of an F32 because I do not see much additional value of the F31-diversity fellowship I received above having a T32 as a predoc.

1. The T32 position seemed easier to get. I assumed that the number of T32 postdoc positions was greater than the number of F32 positions and a higher "success rate" for the T32 position compared to F32. Relatedly, as I meet NIH criteria for being from an underrepresented group, if a T32 position was not available, additional funding could be provided to open a slot. Therefore, an F32-diversity mechanism, like the F31-diversity, would make the T32 and F32 more comparable.
2. On my T32 I meet with the other trainees monthly, giving me the opportunity to receive feedback and to form connections. This is not inherent to an F32. An F32 would be more appealing if monthly/quarterly meetings of other F32 awardees was organized by the funding agency.
3. The T32 appeared to have more opportunities to have face time with senior faculty. NHLBI T32 fellows present orally at the AHA Epi/Lifestyle conference. This session is attended by the T32 faculty members across institutions. As an NLHBI F31-diversity fellow, I was not offered an opportunity to present at this session. I emailed the NHLBI pointing out this issue but was told it was logistically difficult to open the session to F-fellows. This would be one way of addressing perceived inequity between T—and F-fellows.
4. Because of writing the F31 grant, I didn't have as much time to devote to publications. If I were to write an F32, I felt I would be further behind, affecting my faculty applications. Data number of publications, citation stats, and placement into academic positions would make it clearer how publications/grant funding are considered.

Proven or promising external resources or approaches

Student Loan Forgiveness

1. I am unclear on whether being a T32 fellow's position counts towards the Public Health Loan Forgiveness program. Clarity would be great.
2. LRP programs should be expanded, and eligibility criteria clarified. For example, what does "an environment that inhibited the individual from obtaining the knowledge, skill, and ability required to enroll in and graduate from a health professions school" mean given that to be eligible you did complete graduate or health professional school? To make things clearer, why not apply (or at least reference) the same NIH criteria for being from a disadvantaged background: https://extramural-diversity.nih.gov/diversity-matters/disadvantaged-backgrounds. Also, why not make the T32 training programs inform trainees of this opportunity. This would help offset the lack of benefits and low stipend levels that make it difficult for researchers to choose to postdoc.

Response 2108

Perspectives on the postdoc roles and responsibilities

The postdoc position is a research-focused position which enables one to expand their technical expertise through the addition of new skills and techniques, explore new research areas of interest, make additional

academic connections, and publish additional papers; all in preparation for starting their own independent research program at a university or research institute. Postdocs generally have more independence than graduate students and better benefits (health insurance and pay), but also fewer protections. I view an academic postdoc as an essential step if my goal is to be a professor at an R01 institution and a beneficial step for landing professor positions at almost any institution. However, I have numerous friends who have landed positions at primarily undergraduate institutions without completing a postdoc. My personal career goal is to teach, and I have been told that teaching experience is the most important asset that I can gain in addition to a PhD if I want to work at a primarily undergraduate institution. Unfortunately, the number of postdoc positions that including a teaching a component are very limited.

Fundamental issues and challenges

The success of a postdoc is even more contingent on the advisor than that of graduate students because while graduate students have a committee and program that can stand by them in the event of conflict, postdocs are on their own and get very little departmental support. Postdocs generally have fewer training opportunities available to them. For example, training grants at my university provide up to 12 trainee slots for graduate students and only 0-2 trainee slots for postdocs. Postdocs are more isolated and are given fewer opportunities to present their research (compared to both graduate students and faculty). I have witnessed a PI ruin a postdoc's career out of spite; and despite having had a successful PhD and supportive PhD advisor, the postdoc had no means for recourse when it came to his word versus that of the PI and so was forced to leave academia. As a member of the lab in which this happened, I know that the PI spread rumors regarding the postdoc that were entirely false, but other PIs are always going to believe the PI over the trainee. Furthermore, the PI not only slandered the postdoc within our institution, he also spread false accusations to other PIs in the field who had offered the postdoc a position. Witnessing this event greatly demotivated me and all the other trainees in the lab from pursuing an academic career path as it highlighted how uncertain that career path is and revealed how truly vulnerable postdocs are. Another thing to note is that most PhD scientists will make significantly (even double) the salary if they go straight to industry rather than completing a postdoc. This factor combined with the uncertain of job prospects following the postdoc leads many people to choose not to pursue a postdoc.

Existing NIH policies, programs, or resources

1. Provide a means for recourse in the event of conflict and/or build in greater protections for postdocs who received fellowships. The postdoc mentioned above held a NRSA fellowship, which provided some financial protection. However because the project was so closely tied to the advisor's research, the advisor was still able to end the postdoc's academic career by slandering him to everyone in the field. Perhaps there could be a mechanism for reporting or something that holds the advisor accountable for good conduct.
2. Improve the parental leave policy and require institutions to follow it. For example, I had a child when on a NIH T32 fellowship. The NIH policy was that I should have 60 calendar days (8 work weeks) of paid maternity leave. However my department's policy only allows for 6 weeks of paid parental leave, and so I had to forgo 2 weeks of paid maternity leave because my department argued that as their employee, the departmental policy superseded the NIH policy. This was not fair. Also, I would recommend that the NIH increase the amount of paid family leave to 12 weeks. Federal law (FMLA) requires public agencies to give employees 12 weeks of unpaid, job-protected family leave. Most postdocs are employed at public universities and so are already eligible for 12 weeks of unpaid leave. One way to enhance postdoctoral training would be to ensure that the postdoc is paid for the full 12 weeks instead of just 8 weeks.
3. Provide concrete tax directives or services. NIH fellows should not be required to pay self-employment tax. However, very little information is given regarding how to file taxes on fellowship money and this creates a huge disparity between NIH fellows. NIH fellows should be provided with concrete, specific information regarding how to complete their taxes.

Proven or promising external resources or approaches

1. Build in protections for postdocs. This could be done by requiring postdocs to identify 2 additional mentors who can serve in a way similar to that of committee members for graduate students. This requirement could be added to postdoc fellowships as contingency for the postdoc to complete within 6 months of starting the fellowship. That wouldn't change the application process and would give the postdoc time to identify faculty at their training institution who would be appropriate.
2. Provide specific information regarding how to file taxes on fellowship income.
3. Improve the family leave policy (make it mandatory for the hosting institution to comply with NIH policy and increase the number of paid weeks from 8 -12).
4. Diversify the postdoc position by increasing the number of teaching postdocs and providing additional career development support through NIH fellowships.

Response 2109

Perspectives on the postdoc roles and responsibilities

The postdoctoral position is the opportunity to deepen your research ability, knowledge, and further develop your career as researcher. It is the opportunity to expand upon the skill sets obtained in graduate school and extend to more difficult questions. The responsibilities and roles of the postdoc include collaborating with the PI in your lab—this should be a partnership where you are working towards a common goal. The postdoc is working through the more day to day details as they apply the the larger questions. The PI can aid the postdoc when they are stuck on a particular idea or topic, and also guide the research from the higher level steps and objectives in the research.

Fundamental issues and challenges

A lack of support. Salary is really tough—many of us are wanting to start families, or have families, or wanting to buy a house and this salary is so low for the level of degree required as a postdoc. Lack of information—it has been nearly impossible to figure out the correct way to file taxes as a grant-funded employee. The affiliated university provided no information and the NIH website has no obvious place to request copies of your of 1099 or other tax forms. Really appreciate the 5k travel/lab funds though. As a computational researcher, this is a significant amount of funds for my conferences which is greatly appreciated.

Honestly—I dont know how this gets fixed, but every postdoc I speak with, we just don't feel like we even have a shot anymore to get an academic position. From small liberal art schools now requiring and pulling heavy hitting researchers, and the 'perish or publish' mentality.

Existing NIH policies, programs, or resources

There needs to be substantial changes in the vetting of directors and PI's for the university affiliated grant programs. I am a T32 postdoc. Within a 3 month period, all of three of the female senior members left the lab (myself, a fellow postdoc who came into the lab before me, and the lab manager.—all having our doctorates). This lab was incredible sexist and toxic. The male postdoc and undergraduates were provided with more resources, opportunities, and mentorship than any females in the lab. I will only speak on my behalf, but I will note that speaking with the two other senior females this is a consistent experience: I was privately provided with no feedback and yet continually criticized on a lack of progress, asked sexist questions about what my current 'drama' is. There were also very obvious data integrity and research integrity issues that the PI perpetuated and permitted.

When reaching out the the co-director of the T32 program in my department to look for guidance and I immediately questioned, interrupted, and dismissed. The co-director concludes the meeting stating to "lower your expectations of your PI, he only wants to talk when you have results." This co-director has spoken to my about my lab situation in from other other T32 postdocs and graduate students.

Honestly—there's so much more but there's a word limit. This experience continues to plague my career and professional life as I suffer now from extreme work related anxiety and panic attacks, especially with the required continued interaction with the co-director. This experience has been detrimental to my mental health and well-being. I will never do another postdoc after this experience due to the lack of support and compassion from all levels within this program and through the university.

Proven or promising external resources or approaches

Again vetting of the supervisors of the program, respect for the postdoc, and better resources with regards to information about the program, documents and specifics with the contract (like the payback), and a higher salary.

Response 2110

Perspectives on the postdoc roles and responsibilities

It should be a mentored research experience, so should have significant mentoring and training in both research methods and professional development (grant writing, applying for a job, writing papers, giving talks, etc.), not just an opportunity for a professor to use a bright , highly motivated and highly trained Ph.D. as a technician

Fundamental issues and challenges

Recruitment—for most of the labs in our department, can't afford them with an NSF grant, only faculty with NIH grants can currently afford postdocs

Existing NIH policies, programs, or resources

Expand MOSAIC—mentoring in collaboration with a scientific society, make these kinds of opportunities open to more postdocs, make them available to postdoc members of the [redacted for anonymity]

Proven or promising external resources or approaches

MOSAIC program—the [redacted for anonymity] wrote a proposal with a score of 12—funding that proposal would be a great way to enable organized mentoring of at least 25 more postdocs

Response 2111

Perspectives on the postdoc roles and responsibilities

Academic postdocs should be straddling the responsibilities of being in the lab with continuing to learn critical skills beyond those of the lab within which they are embedded. One of those skills that is critical to ALL scientists is the ability to communicate about their research. While language around these skills has incorrectly labeled them with the term "soft" (which also inappropriate due to sexist annotations), they are fundamental skills for the modern work of scientists. In postdoctoral positions, there is often a responsibility to serve as a mentor to graduate students and even undergraduates in some settings. The ability to communicate science to these students is paramount to a successful research environment. These communication skills also support interdisciplinary efforts as every area of research has its own jargon and terminology that needs to be explained appropriately for understanding.

Fundamental issues and challenges

Postdoctoral trainees do not receive adequate payment to compensate for the time and effort they are asked to put into the position. The lack of flexibility for those who are parents or for researchers who become pregnant during their time as a postdoc is also a significant challenge. Lack of diverse role models, mentors and sponsors in these fields also reduces the sense of belonging in traditionally marginalized groups.

Existing NIH policies, programs, or resources

It is critical to provide funding to support the hiring of individuals who have expertise in science communication. These positions should not require PhDs or even masters degrees, rather proven experience with science communication and science communication training should be the necessary skills to take on these roles. Creating and/or supporting departments within an institution that are responsible for collaboratively doing this work is also important as individuals doing the work alone can much more easily get overwhelmed and burned out. When funding proposals are opened for this type of funding, there should not be a requirement for the PI to have a PhD. Again, it is proven experience in this work that matters most, not the letters that come after their name.

Proven or promising external resources or approaches

Funding to support training programs outside of academia is critical, along with support for training designed within institutions. Partners such as science museums, zoos, aquariums etc. can provide not only excellent, thoughtfully designed communication training opportunities, but opportunities to engage with an audience that is craving current, understandable scientific information. Funding of efforts such as the Portal to the Public Network brings together informal STEM education and communication experts who can provide opportunities rarely available within a particular higher education institution. Oftentimes these institutions train interdisciplinary cohorts of STEM experts, allowing postdocs to learn about science communication efforts in areas beyond their field of research and connect with others who share their interest in communication and frequently broadening participation in STEM.

Response 2112

Perspectives on the postdoc roles and responsibilities

It is a training experience where the postdoc should feel intellectually challenged but supported by their research mentor (the PI).

Fundamental issues and challenges

The pay is not great. also the mentorship is often not great. mentors often do not have any formal training on how to be a good mentor, and above everything else this would improve the quality of life the most (even above a higher pay).

Existing NIH policies, programs, or resources

Training for PIs that take NIH funded postdocs on how to be good mentors. training on timeline expectations and also clearly defined expectations for how the mentor will support the postdoc once they go onto the job market.

Proven or promising external resources or approaches

No response

Response 2113

Perspectives on the postdoc roles and responsibilities

The postdoctoral position is way for me to gain additional expertise and be exceptionally more productive in doing research compared to PhD. Having gained the a doctoral degree, we are more equipped to work on the harder problem, and do great science without having to establish a research lab from scratch. We add immense and essential value to a research lab, where it's the post-docs that either help set it up, establish entirely new techniques in a fraction of the time compared to a graduate student.

Fundamental issues and challenges

The labelling of post-doc as a 'temporary job' is the biggest challenge in quality of life of a post-doc. We are the most skilled people in the entire world and yet we do not have a stable job and sustainable income. This is exceptionally worse in cities with high cost of living (bay area, Boston area, which is my situation). Every little stress in my life is amplified because of the financial stress of being a post-doc—my father falling ill, my car breaking down, not being able to afford housing, dental procedures, getting contact lenses etc. Long-term post-docs have become so common, and yet there has been no change in how we label postdoctoral scientist as a job. The most impactful papers in field currently—'nature, science, cell' are mostly all work led by post-doctoral scientist for almost 5 years and it is a shame that we have to sacrifice our quality of life. To add on this, there are no guidelines or aid from the department in how many paid holidays a post-doc can take, or how many conferences they can attend. This creates a immense imbalance of power between the post-doc and advisor, where it is on the discretion of the advisor to be 'good understanding human being'. I am a passionate about science, and I especially want to work in an academic environment, but every single day I question if it's worth the stress—the stress of worrying about seeing my family enough, having enough money to live a good quality life. It is a shame that having the world's highest honor gives me zero job security, and everyday I find an additional reason to stop pursuing academic research and move to industry.

Existing NIH policies, programs, or resources

NIH grant amounts has not increased since 1990s. Why? Why is the NIH minimum for post-docs not scaled by cost of living in the specific city? Has the NIH minimum pay scale increased according to inflation? Why are are post-doctoral jobs a 'temporary job' when we are advanced research staff?

Proven or promising external resources or approaches

No response

Response 2114

Perspectives on the postdoc roles and responsibilities

Postdocs are the backbone in academic research communities. Having talented post-docs to lead projects and perform quality lab tasks are a critical factor for productive research and discovery.

Fundamental issues and challenges

It's been a challenge to get quality postdocs in academic setting even before the pandemic. The long work hours, low pay and uncertain job prospect are the major contributing factors for the ever-shrinking candidate pool of postdocs. In particular, the situation is extremely difficult for junior faculties who are clearly at a disadvantage in hiring top candidates, even mediocre. In response to the issue of general low pay, NIH has raised recommended pay scale year over year for postdoctoral fellows. However, the standard budgets for grants like R01 haven't been increased for two decades. As a result, PIs can only afford to sponsor fewer postdocs than they were able to hire before.

Existing NIH policies, programs, or resources

1. To create more funding opportunities for international trainees
2. The career path from postdocs to independent research faculties is extremely difficult, which mostly relies on the ability of obtaining fundings. It is a well-known fact that international researchers are the driving force in most bio-research labs. Most graduate students with the US citizenship are no longer considering postdoctoral training within the academic sector. However, there are not much funding opportunities for international trainees with working visas.

To raise the standard budgets for major research grants like R01 so PIs can spend more on personnel.

Proven or promising external resources or approaches

No response

Response 2115

Perspectives on the postdoc roles and responsibilities

It is a transitioning position, for people who has finished graduate training but did not find a long term position.

Fundamental issues and challenges

Postdoc is a low paying but demanding position. The quality of life is lower as compared to graduate students and faculty members.

Existing NIH policies, programs, or resources

Lots of postdoc fellows are not from US. Polices do not help these foreign fellows.

Proven or promising external resources or approaches

No response

Response 2116

Perspectives on the postdoc roles and responsibilities

Postdoc should be a term-limited training position. Postdocs should enjoy protected status that prevents them from doing administrative work (ie non-training activity).

Fundamental issues and challenges

the pay is quite low and, what's worse, many benefits are not extended to the posdoc! For example, many universities offer a matching contribution to their employees' 403b, but postdocs are excluded from this.

Existing NIH policies, programs, or resources

should include language that protects the postdoc from being assigned busywork or administrative duties. The postdoc should be dedicated training period.

Proven or promising external resources or approaches

No response

Response 2117

Perspectives on the postdoc roles and responsibilities

Develop skills and knowledge for independent scientific career (which can be in an academic or non-academic settings). Most postdocs are very highly trained and independent and labs provide environments to grow.

Fundamental issues and challenges

Cost of living: it's almost prohibitive to live without roommates in Boston, or have kids on postdoc salaries.

Long term financial security: I'm in my mid-30s and don't have a stable saving for retirement—postdocs are not considered full time employees in our institution so they don't get retirement benefits.

Long term job security—there are not enough academic positions after postdoc and expectations are higher and higher leading to longer postdocs. It's not sustainable.

Existing NIH policies, programs, or resources

Extend the k99 deadline

Increase NIH funding so that funding allocation for salaries is better balanced to the cost of living.

Proven or promising external resources or approaches

No response

Response 2118

Perspectives on the postdoc roles and responsibilities

Responsibility of a postdoc includes research, keeping up to date with the literature, writing, teaching, admin work, grant and funding applications, designing experiments on top of other things.

Fundamental issues and challenges

Is there any industry where one person does the job of 10 people (as listed above)? Somehow it has become characteristic of academic jobs, which is not good.

The pay is much lower for the technical skills postdoc bring to the job. I am a postdoc and I earn much less than a professional cleaner if we both work the same hours!

Not enough emphasis on work-life balance.

Not enough emphasis on skills acquisition and career development.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 2119

Perspectives on the postdoc roles and responsibilities

As a psotdoc, I see myself as a junior researcher. I am still gaining important mentorship, but day-to-day my focus is on producing research, helping to make sure the lab group runs smoothly, and mentoring younger members of the lab. As a postdoc, I feel like I mostly am working for myself, for my own success, and I enjoy working with my PI as a source of guidance rather than a demanding "boss". I pursue a mix of my own ideas and those of my PI, but I aprpeciate having someone there to help me make decisions and interpret my results. I see my postdoc as a time to develop my thinking and produce foundational work that I will build on in my own lab. In this way, I think postdocs are essentially equivalent junior staff members who recieve mentorship from senior staff members—say a police detective recieving mentorship from their lieutenant—rather than students. No one would call the junior detective a "student" simply because they are early in their career and still work under a supervisor. Many professions involving working under a supervisor your entire career, so thinking of postdocs as trainees simply becuase they work in someone else's lab really makes no sense.

Fundamental issues and challenges

The primary negative aspects of postdoctoral life come from the idea that we are students and not staff. Becuase postdocs are not at all "students," it is extremely frustrating to be treated as such. For example, at my university postodcs do not reciece retirement benefits that other staff members would. This kind of treatment is not only a bit insulting, it is very disuasive for people considering working as postdocs.

Furthermore, while I generally have found the postdoctoral salary to be quite comfortable, this changed when I unexpecetdly had to contribute to caring for an elderly family member. Suddenly the stipend really is not enough, and if I also had children of my own it would be completely unsustainable. At any rate, it is in no means a competative salary, and many of my friends have chosen not to do postdocs specifically for this reason.

Existing NIH policies, programs, or resources

Increasing basal postdoc salary levels would go a long way. Providing build in, automatic child care support for postodcs would also be extremely helpful. Generally, treating postdocs as professional adults and not students, and giving PIs the resources to hire postdocs competatively.

Proven or promising external resources or approaches

No response

Response 2120

Perspectives on the postdoc roles and responsibilities

I took an academic postdoc to fill in gaps in my CV that I hadn't had experience with during my PhD training. I wanted (and have gotten) experience with several specific techniques and with academic writing. My PI is trying to secure NIH grants based on my work and so my role is to generate preliminary data for those grants.

Fundamental issues and challenges

I relocated to a city in which I have previously lived for my postdoctoral training. When I lived here from 2013-2015, I was easily able to afford to live on my bachelor's degree salary. When I signed my postdoc offer letter, I had budgeted to be able to easily live here on this higher salary, as well. Unfortunately, because of inflation increasing rent and prices for basic necessities to a great degree, I can no longer afford to pay my bills in this city and am looking for jobs outside academia as my savings deplete each month. Furthermore, my PI is not supportive of giving me time or bandwidth to pursue core competencies

other than those directly related to research, and he is entirely focused on preparing me for an academic faculty position, which I do not want.

Existing NIH policies, programs, or resources

Postdoc salaries need to increase to be somewhat competitive with what recent PhD graduates can get in the industry sector, or qualified graduates will continue to choose not to do academic postdocs if they have non-faculty career aspirations. I did an academic postdoc because I wanted to gain additional skills before getting a permanent position, and I feel like I made a bad choice that will impact me financially for years by doing so. To increase postdoc salaries, NIH grant amounts also need to rise (and my understanding is that they haven't since 1999). This is unacceptable given the amount of inflation in the last 24 years. Furthermore, I declined a competitive T32 grant because it would have made my tax, health insurance, and retirement savings situations much more complicated. It is not acceptable to tell professionals in their 30s that they cannot contribute to retirement in order to take a competitive training grant.

Proven or promising external resources or approaches

The industry approach is to pay recent PhD graduates commensurate with their experience. NIH could learn from that. NIH's own postdocs that work on site in Maryland are paid more than the NRSA standard, so the institutes are clearly aware that the NRSA minimum is not high enough.

Response 2121

Perspectives on the postdoc roles and responsibilities

Postdoctoral position is employment following completion of your PhD that provides you with the opportunity to further develop the skills necessary for your career. For example, if one wishes to persue a career as a faculty member in academia, their postdoc should provide them with opportunities to teach, write grants, manage team members etc. If a postdoc wishes to persure a career in industry, their postdoc should provide them with opportunities to network or work with industry, develop management skills, attend business classes etc.

Fundamental issues and challenges

Salary is very low in comparison to PhD graduates entering industry. Positions are unstructured and do not necessarily provide the skills needed for next steps in career. Supervisors are known to bully, over-work, and exploit their postdocs (especially vulnerable international postdocs). J1 visas require you to leave the US to extend your visa—something highly inconvenient and often at the expense of the postdoc. Some postdocs give up on traveling internationally as their expired J1 visa would not permit them to re-enter the US (this is legal as long their DS2019 is still valid).

Existing NIH policies, programs, or resources

Increasing the funding for postdoc positions in grants. Increasing the awards/programs available to international postdocs.

Proven or promising external resources or approaches

No response

Response 2122

Perspectives on the postdoc roles and responsibilities

In practice: a workhorse for exploitative labor, coupled with opportunities for learning that are only available for those with the know-how to self-advocate. Ideally, it would be a well-paid role that clearly acted as a stepping stone to the next desired role, with mentorship to get people there.

Fundamental issues and challenges

You need to pay post docs way, way more money. They are being paid probably half of what they are worth.

Existing NIH policies, programs, or resources

NIH high risk high reward is an excellent program. We need more like ti, where post-docs are encouraged to get independent funding that allows them to grow and explore and contribute freely and with minimal strings. Post-doctoral funding is also woefully inadequate. Many post-docs have families ad live in large cities. The current post-doc compensation structure is about 1/2 of what it needs to be to make this career commensurate with alternatives. It is a shame that our nation funds science in this Darwinian way, that disproportionately affects those without the family or community resources to make it endurable. We are losing talent.

Proven or promising external resources or approaches

We need to switch to demand-side, rather than supply side science. We should not be funding science in this nation solely through grants. We need to advocate for a broad scientific ecosystem that has well paid roles for distributed networks of creative work—not just at the NIH, that does not require climbing the academic ladder (within academia) or exiting to industry (outside of academia) in order to focus on doing goo, creative, thoughtful, and appropriately compensated research. We are stunting out ability to grow intellectually as a nation.

Response 2123

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

The most critical issue is the current wages. Most supervisors pay the post-docs based on the NIH payscale. The payscale for postdocs is utterly insufficient to survive in key cities such as California, New-york, Boston, etc. For example, in Boston, after taxation, a Post-Doc gets around 3500-3800. The minimum rent of a 1-room apartment is 3500. At the same time, graduates who shift to the industry are offered four times higher salaries. In addition, most of the post-docs are from other countries. It is extremely difficult to get permanent work authorization in the USA. Since they have to find a job back in their countries within a short period, it creates a discouraging environment.

The overall quality of life in PostDoc environment is extremely grim. Extreme workload, high expectations from the lab, poor wages, and no opportunities make it one of the hardest journeys.

Existing NIH policies, programs, or resources

Increase the NIH payscale considering the high costing cities where the most renowned research labs are located.

Proven or promising external resources or approaches

No response

Response 2124

Perspectives on the postdoc roles and responsibilities

All junior scientists should receive science communication training as part of their NIH award.

Fundamental issues and challenges

No response

Existing NIH policies, programs, or resources

Proven or promising external resources or approaches

No response

Response 2125

Perspectives on the postdoc roles and responsibilities

To me postdoctoral position is a full time job that the individual is doing to build their own research idea and gain more independence for their project, more than they had in their PhD. More importantly, I view it as gaining more understanding of setting ones own laboratory in the future or gain more technical skills to be more competent for industry jobs. It is also a period where the individual does more mentoring and grant writing to gain funds to start their own lab or for doing postdoc in the PIs lab. To me its an extended training in a full time job similar to what an individual needs when they start at a new company in an industry job.

Fundamental issues and challenges

I think the biggest challenge for why most graduate students do not want to do a postdoc is the pay. As graduate students we are already in significant amount of debt/financial woes, so if one decides to do a postdoc it is again the situation is just the same and gets worse especially in bigger cities. With the rising cost of inflation and the salaries staying the same its more than tempting to avoid academic postdocs and go for either industry postdocs or full time industry jobs. Plus the pay being low is also coupled with really poor benefits that is below par when compared to full time employees in the academic institution. Even PIs who have excellent funding refuse to pay more than NIH standards because the NIH has set basic salary expectations for postdocs. I really think if the salary can be upto industry postdoc standards that would significantly improve chances of people considering postdoc positions in the future. Postdoc really have a family to and their own health expenses to think of like every other individual. In addition to that NIH should try to have an overall 2-year contract for postdoc positions. I think its too much pressure for having just one year contract immediately after grad school.

The current strike by [redacted for anonymity] postdocs basically tells that postdoc conditions are really bad. Employees should not be going on strike to get paid for fulfilling basic needs of life.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 2126

Perspectives on the postdoc roles and responsibilities

Charity work for institutions and supervisors who won’t respect me much

Fundamental issues and challenges

Salary, hours worked per week, vacation time, and the fact that at any moment any member of your workforce can double their salary by leaving.

Existing NIH policies, programs, or resources

Improved salary, reduced hours.

Proven or promising external resources or approaches

Improving postdoctoral salaries.

Response 2127

Perspectives on the postdoc roles and responsibilities

Post doctoral position for me is an opportunity where I can build on my PhD skills, apply those skills to generate data and apply for fundings. It’s a stepping-stone to get to a faculty position where I could focus on the skills and roles I did not take or didn’t have to take as a PhD student.

Fundamental issues and challenges

1. Yearly contract
2. Ending in job termination if one doesn't bring grants within 2-3 years
3. Low pay, low pay, low pay
4. No/minimal benefit
5. No childcare support
6. No holidays or expectations of PI for us to work through weekends and holidays
7. Absolutely no work-life balance
8. Industries now offering everything that academia doesn't

Existing NIH policies, programs, or resources

1. Increased PAY!!!!
2. More funding opportunities for post-docs and early careers
3. Fellowships allowing benefits in it's cost
4. Universities generally allowing for benefits including child care, and NIH proving extra fund to cover for it
5. Treating post-docs like employees and not just "trainees", offering holidays, retirement plant. We are professionals too

Proven or promising external resources or approaches

No response

Response 2128

Perspectives on the postdoc roles and responsibilities

The postdoctoral fellow can have several responsibilities. They must support the research of their department while developing in to an independent investigator. For clinician scientists, the postdoctoral fellow must also support the clinical enterprise.

Fundamental issues and challenges

The three primary issues inhibiting recruitment, retention and overall quality of life is

1. lack of established training/career development pathways,
2. lack of support/resources to pursue existing pathways, and
3. lack of financial incentive/percieved lack of unfairness to work for no financial reward.

Existing NIH policies, programs, or resources

The NIH can consider smaller grants for early investigators that will introduce them to funding mechanisms, pathways and resources. Greater amount of loan forgiveness opportunities should also be considered.

Proven or promising external resources or approaches

The NIH can consider smaller grants for early investigators that will introduce them to funding mechanisms, pathways and resources. Greater amount of loan forgiveness opportunities should also be considered.

Response 2129

Perspectives on the postdoc roles and responsibilities

Right now I am viewed as cheap labor—my leadership has mentioned several times that to address the clinic's provider understaffing, they are intentionally hiring postdocs to see a high pt load because our

stipends are so low. They are clearly placing my clinical load as a greater priority than my training. With the salary, i am barely able to afford to live above poverty, and this, coupled with the high patient load, is leading to very high burnout and I am looking at leaving my postdoc for an industry position.

Fundamental issues and challenges

The low pay and industry providing a decent wage made accepting a postdoc position a very difficult position. I really want to get further training, but becuase internship and graduate school stipends are so i am financially not able to live on the postdoc salary.

Existing NIH policies, programs, or resources

it might be good to take a model more aligned with residency, where we have our doctorates and we are paid a living wage for my city. Here is a published guideline for one city: 1. Yalcin , E., Martinez-Corral, R. & Chugh, M. Retaining postdocs by recognizing their worth. Nat Biotechnol 41, 296-298 (2023). https://doi.org/10.1038/s41587-023-01656-4

Proven or promising external resources or approaches

a cap or limit on direct hours that a postdoc is allowed to see (so we have protected training time). This would stop business-related needs from overworking us and placing our RVUs or profitability over our training.

Response 2130

Perspectives on the postdoc roles and responsibilities

A postdoctoral position allows for advanced and enhanced scientific training both within a classroom and in the lab. I chose a postdoctoral fellowship and a K12-mentored fellowship(ASERT/IRACDA) in order to both get experience/training in the lab and within the classroom, specifically as it relates to minority-serving institutions.

Fundamental issues and challenges

Lack of additional training and mentoring available for all postdocs. Our institution does NOT provide tuition remission for postdoctoral fellows, so postdoctoral fellows cannot take classes which could DIRECTLY enhance their training/professional development. We also DID NOT have a postdoctoral affairs office nor a director of postdoctoral affairs until JUST this last year. We also JUST began a postdoctoral association, which is run by postdocs FOR postdocs. It’s difficult to get buy in from multiple departments because postdocs aren’t allowed time for these activities, historically. I also think a HANDBOOK for how to mentor/train a postdoc is CRUCIAL to increasing opportunities to enhance recruitment, retention and quality of life.

Existing NIH policies, programs, or resources

More funds available for academic institutions to CREATE Postdoctoral offices, SPONSOR Postdoctoral associations, RESOLVE postdoctoral issues fairly and equitably, and FUNDS available to support professional development and networking activities for postdocs. It would also be nice to ACTUALLY GET PAID PARENTAL LEAVE and PROTECTIONS, which currently does not exist at my institution. Additionally, we are NOT ELIGIBLE for our state retirement plan, even though we are ‘employees.’ I really wish I could save for retirement during this time of training. I also wish I made more money, like enough to actually start a savings account.

Proven or promising external resources or approaches

You could improve postdoctoral training ecosystem with a SUPPORTED postdoctoral affairs office, a director of postdoctoral affairs, and ACTUAL office for these individuals, websites for submitting concerns, supporting and developing postdoctoral associations at various institutions to first assess the individual problems, because they seem to all be different at different places. Additional ways to support postdocs could be LOAN REPAYMENT programs, which could help reduce the BURDEN that many FIRST generation college/grad school students may face.

Response 2131

Perspectives on the postdoc roles and responsibilities

In my experience, a postdoc position is the stage where postdocs get to run with their own project, so it is quite different from grad school. I know many do not feel they are still trainees, but perhaps this is semantics and there is a better intermediary word for this period.? If this really is not a period of additional training, senior faculty would need to be educated, because they definitely consider this additional training to help launch the postdocs onto their desired long-term career path. It also doesn't seem industry would rely so heavily on most postdocs spending at least a bit of time in an academic lab if there wasn't some component of training involved. (I admittedly am a lay person, so this is just what I have observed from my vantage point.)

Fundamental issues and challenges

Specific to the NRSA, the health insurance and tax issues are an enormous barrier for postdocs. While receiving the NRSA is supposed to be prestigious, fellows feel like they are being penalized when they accept the funding. The stipend issue is a very out-of-date funding vehicle and needs to be modernized into a normal grant. If the issue is partly the overhead, an NRSA grant (not stipend) without any overhead would still be a huge improvement--and institutions would still save tons on needing less manpower for the health insurance, tax, and stipend pay issues.

I have explained to countless fellows that NIH doesn't expect fellows to be paid at the NRSA scale on the PI's R01s--the NRSA rate is for when a fellow is awarded their own NRSA grant or training slot. However, most fellows think that NIH is increasing their PI's budgets annually to cover the NRSA increases. I don't know what the answer is to better education (and eventually increased budgets!), but fellows would at least feel better if they understood the fundamentals. They also think all the overhead goes to the PI's lab or our Program--so they feel there is all this money that is being kept form them, when in fact, budgets are flat, without cost-of-living increases, and the overhead goes to the institution.

Existing NIH policies, programs, or resources

In addition to the above, it would be great if there was a way for PIs to supplement NRSA salary with federal funds as long as it is assured there is no double-dipping. Fellows have to be supplemented, especially in expensive cities, thus realistically, they have to work on other projects. Sometimes this is a barrier depending on a PI's portfolio.

Proven or promising external resources or approaches

In general, postdocs do not learn grant or personnel management in grad school. This is a part of the training during their postdoc, which I take very seriously to help educate them about, and it is beneficial even if they will go right to industry.

These are complex issues and I truly appreciate the sessions and this survey. Thank you!

Response 2132

Perspectives on the postdoc roles and responsibilities

I view it as a position to start an academic career.

Fundamental issues and challenges

The fundamental issues is that it is expected of a postdoc to work all the time, without a possibility of enjoying another activities necessary for a good mental health. Also the salary is not even comparable with the salary in the industry, which is an important factor for everybody's life.

Existing NIH policies, programs, or resources

I would say that it is necessary more benefits, like the right of working specific hours in order to have free time to enjoy other activities.

Proven or promising external resources or approaches

Probably improving the salary.

Response 2133

Perspectives on the postdoc roles and responsibilities

Many PIs simply see postdocs as older graduate students and treat them as such. They overwork them in the laboratory work aspect and don't care whatsoever about their career aspirations. Other PIs do allow postdocs to utilize their time for further laboratory work training plus a career development component. The latter would be preferable.

Fundamental issues and challenges

Extremely low pay for individuals who have 2 or more degrees. Our university doesn't offer retirement matching and provides very few benefits for postdocs. Many industry positions don't require a postdoc step anymore or are willing to hire a person for a postdoc position at the company. Industry is alluring, due to the higher pay and better benefits.

Existing NIH policies, programs, or resources

Make stipends higher, require that postdocs receive benefits like other full-time employees, and require PIs to allow at least 33% of the postdoc's time to be dedicated to career development activities.

Proven or promising external resources or approaches

No response

Response 2134

Perspectives on the postdoc roles and responsibilities

I new the post-doctoral fellowship as a stepping stone to independence. I want to develop key skills of a principal investigator, including the ability to conceptualize research programs, rather than just experiments or series of them. I will also focus on advanced skills development as well as identifying an preparing to move into an area that I will focus on in my own academic research as an independent investigator.

Fundamental issues and challenges

The biggest challenge is the outdated assumption that a postdoc is only valuable if a candidate changes institutions. I have encountered this repeatedly from individuals employed at the NIH as well as more advance colleagues at my own institution. Graduating PhD recipients have the most compelling interest in their career and decisions not to relocate should be respected and welcomed. There are many valid reasons for not relocating or changing institutions, including continuity, familiarity with key resources that will be important to a future career at the current institution, family relationships and personal choice. Perpetuating the myth that training is better or more effective if a candidate moves imposes a significant burden on career advancement. People who wish to move should of course feel free to do so, but people who do not wish to move should be equally free to stay where they are without incurring some implicit penalty on career advancement. Compensation is an additional impediment, both in terms of salary and benefits. It is better at the postdoc level than the graduate student level, but expecting a postdoc to spend five or more years in a low-pay situation is unrealistic. If postdocs are valued, they should receive enough compensation to be able to live at a reasonable level during the fellowship.

Existing NIH policies, programs, or resources

The implicit and sometimes explicit requirement to relocate in order to obtain a post-doctoral fellowship. The requirement and emphasis on relocation should be removed from all career development awards (the entire K program). The only way to adequately do so is to eliminate consideration of the applicant's current and proposed location from the award process.

Proven or promising external resources or approaches

Incentivizing PIs to participate more in mentoring post docs would be very helpful. The incentives should address both the NIH fellowship application process as well as career advancement mentoring. Among other things, PIs should not assume that an applicant at the postdoctoral level will draft sponsor statements and then hand them over to the PI for signature. The PI should be an active participant in the process. Not sure how to go about requiring this but it would enhance the process.

Response 2135

Perspectives on the postdoc roles and responsibilities

I view the post-doctoral position as a waste of my time--I already spend over 5 years of my life making hardly any money. I have no savings and need to start earning money towards retirement and my own personal savings. I have no desire to pursue a faculty position in academia, and even if I wanted to, I am under no illusion that I would be one of the few to actually make it into one of these positions.

I think the independence gained from a post-doc can be very valuable, however, I would rather pursue an industry post-doc where I will gain skills that will be directly applicable to gaining an industry-level position, all while earning a livable wage.

In short, academic post-docs don't offer nearly enough money and don't always equip you for the difficult transition to industry out of academia.

Fundamental issues and challenges

The cost of living is increasing, and in many cities you cannot simply maintain a reasonable standard of living alone on a post-doc salary. For the amount of time and effort put into a post-doc, it seems like an obviously choice not to pursue it.

Existing NIH policies, programs, or resources

Make schools pay post-docs more.

Proven or promising external resources or approaches

Better pay, better benefits.

Response 2136

Perspectives on the postdoc roles and responsibilities

A stepping stone to an academic position. Academia is no longer revered and many see it for what it is—a sexist hierarchy that is holding onto "the good old days" .

I will not pursue an academic career and I will advise any students I mentor to not stay either. I have tried to see both the good and bad sides of it. Many PIs and labs hide the bad, which is worse because then you are surprised and stuck in an abusive environment where everyone tells you it's normal and there is no help to get out.

Fundamental issues and challenges

Lack of pay, especially among inflation.

Many people don't want to stay in the same system that didn't care for them as graduate students. The people who do stay tend to uphold the current system—pushing minorities out even faster. Why stay in a system that will not change.

The constant need to publish first—the fear of one's research not being considered interesting enough to get funding. The competition is crazy and while science is my life I cannot be stressed over funding for my entire life. I want to be financially stable and have the opportunities to travel and live life outside of a lab.

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 2137

Perspectives on the postdoc roles and responsibilities

The postdoctoral position is an early career training period designed to give young researchers additional training. Ideally this training will further their CV and they can learn new techniques and gain more responsibilities.

Fundamental issues and challenges

The pay is atrocious. I am only able to continue this position because my family helps me out financially. I would make 2-3 times in industry what I make in my postdoc. Seriously. It's unreal how little we are paid.

Existing NIH policies, programs, or resources

Increase the pay.

Proven or promising external resources or approaches

Pay more money. Please.

Response 2138

Perspectives on the postdoc roles and responsibilities

No response

Fundamental issues and challenges

Salaries are too low

Existing NIH policies, programs, or resources

No response

Proven or promising external resources or approaches

No response

Response 2139

Perspectives on the postdoc roles and responsibilities

When I began my career as an undergraduate intern, I viewed post docs as high level talented mentors, and was under the naïve impression that they were paid based on their level of expertise and talent, and must've had great benefits for being on the other side of a terminal degree. Now that I'm a fourth year graduate student closer to that potential career step, I realize nothing could be farther from the truth. Now I see post docs as high level scientists that failed to secure a job in time for defending their PhD and had to settle for the less than ideal jobs that are widely available and severely underpaid. It is billed as a short term training position (2 to 3 years) that quickly and easily ensnares people for 6 to 8 years, or in many cases people do multiple post doc positions, to chase the impossible goal of becoming a principle investigator.

Fundamental issues and challenges

Post doctoral trainees do not make livable wages, have less benefits than employees (no retirement contributions, no overtime or holiday pay, no maternity leave, lower quality health insurance) and are largely exploited to carry out duties that are the responsibility of the principal investigator, such as 'ghost reviewing', managing the lab, or being solely responsible for student mentorship. While reviewing manuscripts and mentoring students are important experiences for post docs, I have seen it get to a point where the PI is not involved at all, yet takes credit for these efforts. Post docs have no protection from any type of exploitation. Additionally, post doc positions fail to train scientists for industry or other scientific career choices beyond academia. These are not necessarily blanket statements, plenty of people have had great experiences as post docs, but I do feel that these issues are pervasive enough to turn most modern student's stomachs when considering post doc positions. The jobs beyond the post doctoral step are so

scarce that doing a post doc is an unwise choice for anyone that intends to have a valuable, versatile career that also respects living a fulfilling life outside of work.

Existing NIH policies, programs, or resources

The NIH student loan forgiveness plan is the only program I can think of that provides a valuable benefit to scientists who pursue postdoctoral fellowships. Expansion of grant opportunities specifically for post docs could help also.

Proven or promising external resources or approaches

Intense reform is required to change the working environment and culture that maintains the exploitation of post docs. Reforming academic culture may take generations, especially when the generation of scientists that currently holds the most power are unlikely to embrace change. First and foremost, the salary for post docs needs to be raised to a livable wage that is comparable to other post-terminal degree jobs. The benefits must also be improved. Graduate students don't have retirement contribution benefits, and then go on to another position where they still don't have that benefit? How is that a wise financial move in any way to sacrifice over a decade of not receiving standard matching for retirement funds? Training for other careers beyond academia should also be implemented. Industry has begun to view postdoctoral fellowships as a weakness, not a strength. Students who are interested in pursuing industry are not willing to harm their resume by doing a post doc. There needs to be greater opportunity beyond post doctoral positions, because it is now a dead end road that many talented people get stuck in, often times causing them to leave science all together.

Response 2140

Perspectives on the postdoc roles and responsibilities

It is a training position where new PhDs take what they learned during their graduate training and significantly build on it to become independent scientists. It should be in a field of study in which they want to have a career. Mentors should provide individualized training to assist the postdoc in reaching his/her/their goals.

Fundamental issues and challenges

The large time commitment and highly competitive nature of academic postdoc fellowships inhibit too many of today's young scientists that want to have work-life balance now and not delay it. The long hours it takes to generate sufficient data to have very high impact first author papers for those that want top jobs in academia or industry take longer than it used to because of the size of such papers now (over 100 individual figures/manuscript). Although there is more support for those with children than years past, there is not enough support. There is insufficient NIH funding for trainees across the U.S., and a lack of understanding at NIH that postdoc training takes longer now, which requires more funding for longer.

Existing NIH policies, programs, or resources

Increase the number and extend the funding for grants focused on postdoc training (T32, F32, K99/R00, K08, K22, etc.)

Allow non-U.S. citizen/non-green card holders to be on NIH training grants.

Provide funding for institutions to hire more faculty and staff that only focus on training and career development for postdocs as a supplement for the overworked mentors that have less time to train postdocs in the non-science aspects of career development now.

Proven or promising external resources or approaches

Need NIH to build bridges to top foreign biomedical institutions that NIH has vetted, making it easier to tap potentially great trainees outside the U.S. The vast majority of universities in the U.S. do not have the resources or the connections to build what is needed for these opportunities.

Response 2141

Perspectives on the postdoc roles and responsibilities

An academic postdoc should a early-stage investigator with significant support from mentors and institutions to be successful investigator(provide training in leadership position to manage and develop a research team and collaborative projects, writing successful grant proposal, developing new large skills for future project), manage a small team and project

Fundamental issues and challenges

There is an absence a clear explanation of recruitment (we observed a lot of network support for only white men to recruit them but absence or discrimination for other) and there is lack of providing a good salary and work/life balance for the level of skills that a postdoc has.

The PIs use expertise of some postdoc with previous experience but do not want to recognize and help them for the career of their postdocs.

Existing NIH policies, programs, or resources

Increase of base salary based on the previous years of experience and skills with increase of salary per year.

Provide access for better training and network for postdoc

More clear description of recruitment process and how the American academic system works for foreign people or underrepresented persons without network in an academic research

Proven or promising external resources or approaches

It may be good to look at how industry work to assure to keep their best employees and continue to train them to be good leaders and managers or expert depending on the direction of the person want to go.

To have more long term salary and not short term as in CNRS (FRANCE)

Recognize the role of mentor and provide training for PI to learn how to manage a team and projects!

Response 2142

Perspectives on the postdoc roles and responsibilities

The postdoctoral position is poorly compensated indentured servitude with no guarantee of relief from service. Poor funding opportunities and high competition make the post doc seem less like a stepping stone and transition into a more independent position and instead a high likelihood of never ending limbo. The fear of becoming a perpetual post-doc which is by far the most likely outcome in todays funding situation is a fate that overall career death sounds better than. Transitioning to industry and making an honest wage or changing careers altogether sounds like a far better outcome and has more opportunity for career progression than being permanently stunted as a postdoc. The thought of being a postdoc makes me want to drop out because it is synonymous with career death when it used to be a career stepping stone into a career in academia. If funding outcomes were different and there was data showing that a reasonable percent of postdocs were able to secure funding in a handful of years, then it would make sense. However, the mere thought of becoming a postdoc and just being abused by the system with no recompense is a guarantee that I will change career paths after finishing my graduate education before becoming one.

Fundamental issues and challenges

My hope for securing funding and becoming an independent researcher is dead. There is no incentive to do a post doc if this is no longer a viable option. I really don’t know why you need to do this survey. It should be obvious that humans are motivated by perpetual improvement and if you don’t give them any hope of continuing to grow they burn out. Is it possible to become independent after a postdoc still? Yes, but the chance is so low that the risk isn’t worth it. Especially someone like me who does not have any DEI social credits to my name that could make it easier to secure funding outside of my hard work and track record. I don’t know why anyone, especially in my demographic, would ever do a post doc in this day and age. Period.

For reference, I was originally highly motivated to do a PhD and have a career in academia in undergrad; however, I chose to do the MD/PhD route because I want insurance. I am definitely a PhD research career priority applicant, but the horrible funding landscape made me apply MD/PhD (at a strong MSTP funded institution) to increase funding probability. Additionally, I have the MD as insurance in case obtaining funding is too costly. I am in a very privileged position in that regard compared to many other grad students. I say this to make a point though about just how bad the system looks right now and the lack of incentive to be trapped in a post doc. After 16 years (8yr MD/PhD, residency, fellowship, post dococ) of post ugrad education I could still be trapped in a postdoc and have a hard time securing funding to be an independent researcher. What about all my other colleagues?

Existing NIH policies, programs, or resources

I understand the importance of making our researcher base more diverse and having grants that help people from disadvantaged backgrounds break through the glass ceiling. However, it is to the point where it feels that no matter how hard I work or what my track record looks like, securing funding is like gambling. Increasing funding opportunities that are based solely on merit (in addition to those that help people from disadvantaged backgrounds) would at least give someone like me hope that there is a chance for me to one day transition out of a postdoc.

Proven or promising external resources or approaches

Having postdoc pay that is not 2-4x below industry pay and rekindling the hope of one day securing funding to transition out of a postdoc and not be trapped as an eternal postdoc are critical. Obviously no one expects a postdoc position to pay what is in industry; however, if the pay must be high enough to give a quality of life that is sufficient to consider taking the stepping stone for future career aspirations. Just rekindle the hope of transition one day from a postdoc by improving funding opportunities to a point where it no longer feels futile to try and pay postdocs enough that they don’t feel like they are being absolutely abused.

Response 2143

Perspectives on the postdoc roles and responsibilities

Additional research training to acquire more skills to make you a suitable candidate for a tenure track assistant professor position within academia.

Fundamental issues and challenges

The low salary, poor work-life balance, and no guarantee of a tenure track position upon completion of the postdoc.

Existing NIH policies, programs, or resources

Set the pre-doctoral and post-doctoral stipends higher.

Proven or promising external resources or approaches

Better salary (!!!), formal mentorship, pipeline to tenure track position.

Response 2144

Perspectives on the postdoc roles and responsibilities

I anticipated that this postdoc experience would provide excellent training and mentorship that would situate me for finding a position in my specialty. I anticipated that would be with the group that brought me here for postdoc. I anticipated that the group forming my postdoc training would become a professional home strong personal and mentorship relationships.

Fundamental issues and challenges

I have found almost none of the things I anticipated in coming to postdoc, in fact, I have been severely restricted in my roles, treated in a minimizing hierarchical manner as if I had nothing to offer, no previous training before arriving here, and as if I have nothing to offer to this site other than to break me down so they could build me up in their image. I have felt isolated and professionally adrift to the point of questioning my chosen specialty. When these issues are put in the context of the cost associated of

relocating for a year of training it becomes even more frustrating. And now, the promised option of a second year of postdoc, which would help reduce the personal cost of relocation, has been removed as an option. An intern colleague went to a position paying almost double of what I am earning as a postdoc, so no, I would not recommend an NIH postdoc to current interns based on the experience that I have had at mine.

Existing NIH policies, programs, or resources

Pay us commensurate with our training and the value we add to our sites and make it obvious what the resources of support are for people who encounter toxic training systems like the one I have encountered.

Proven or promising external resources or approaches

No response

Response 2145

Perspectives on the postdoc roles and responsibilities

A training position for a PhD-level scientist that serves as a dedicated time to expand knowledge and skills in a particular field of study, which leads into a productive research career.

Fundamental issues and challenges

No response

Issues and challenges inhibiting:

1. Quality of life and retention: salary is roughly half of what industry pays and does not factor in zip code of where the position is. Many postdocs have a higher quality of life in their graduate studies with part-time graduate assistantships in more affordable areas than they do with full-time postdoctoral salaries in big cities where almost all of the postdoc positions are located.

Existing NIH policies, programs, or resources

Programs:

1. Change the criteria to obtain new or continued NIH funding that focuses on quantifiable advancement in a research field rather than the number of publications the research produces, prestige, etc. These parameters often produce an impossible barrier for anyone coming from a graduate program where the research was not directly funded by a principal investigator's NIH funding, making it harder to have numerous publications or build prestige. These students often learn many skills not found or lacking in traditional NIH-funded research graduate programs to stay competitive, such as varied research methodologies, statistical analyses, technical writing, etc. that are essential to conduct and disseminate research. However, with the current set-up many do not develop productive independent research careers because they are never successful in getting their first NIH grant to springboard their career in a specific field of research.
2. An easier transition to change primary fields of research. Many scientists feel stuck studying research topics that were substantial in the beginning, but overall became "dead ends." However, currently scientists will not change what or how they study their research topics because that is what they built their career on and for a greater chance of continued funding in "publish-or-parish" environments. This particularly impacts postdocs the most since it leads to many principal investigators not having any ideas on how to advance their own research agenda and they instead rely on postdocs to do it for them, who most of the time have to produce results before they have enough time to learn about a principal investigator's research.

Proven or promising external resources or approaches

External resource: U.S. military pay structure.

The number one reason to improve all aspects of the postdoctoral training ecosystem as described in this section is to adequately pay postdocs based on location of postdoctoral training. The U.S. military provides basic pay for a normal salary and an additional housing allowance that is dependent on zip code. A pay structure like the military has will significantly increase recruitment and retention.

Response 2146

Perspectives on the postdoc roles and responsibilities

The postdoc position is unique in that it is both a professional and a trainee position. While the position may have been established long ago under an apprenticeship model of doing science, it is clearly much more than that now. I think it is a valuable position for both trainees and trainers, if not abused and there are equitable opportunities for people in this position, given that they are professionals with an advanced degree. I was in a situation, and still am in a field, where Ph.D.s can take a long time. I have gone through it myself and watched my peers and those who I mentor go through this time in life as both a wonderful time in science and a stressful one in terms of future career and having a life outside of work and the responsibilities it brings.

Fundamental issues and challenges

I think the biggest challenge to being a postdoc at the moment is that you ultimately have to be in a position of privilege in order to be one. Compared with other professional, post advanced degree positions, the salary is low, the benefits are not standard or even available in some cases, and it is not possible to support a family or even yourself living on your own paying rent with only a postdoc salary. In my own case I had a spouse that was at a different stage in his (academic) career (he was faculty) and that's how we were able to make life work. But I would say that my situation is rare and it is much more common for people to be at the same career stage, which causes considerable stress and hardship. Currently, it seems graduate students thinking about postdoc perceive it as a dead-end job, in that the previous promise of a (tenure track or similar) faculty position after a brief stint as a postdoc generally does not exist anymore. There is also a lack of diversity (of all kinds) at the upper levels in academia because of many of these issues, along with there not being many role models for diverse people who have been successful at this path.

Existing NIH policies, programs, or resources

There are at least four ways that existing policies could be updated to dramatically benefit postdocs.

1. Make sure postdocs supported by NIH fellowships are "employees" . At many institutions, an NIH fellowship means the postdoc is no longer considered an employee of the institution and therefore does not receive the same kinds of benefits (health coverage, dental, eye, parking, childcare, retirement, etc.) as those supported by alternate means (including other fellowships that now have updated their rules). The current workarounds are insufficient, and it creates a burden and unfair disadvantage for those on fellowship.
2. Windows of eligibility for fellowships and other funding mechanisms should be increased. Short windows mean that for anyone who's work is on a longer timescale or who takes time for family care is automatically at a disadvantage. While there is allowance for any official leave of absence to extend the eligibility window, it is typically (6-8wks) not enough to extend to the next regular NIH deadline.
3. Family leave should be extended. Postdoc is a professional position that is held by people who can bear children or want a family often exactly at the point in life when they would want to start said family. Grant eligibility windows should be extended by a minimum of one year (as ESI status can be extended). Official leave should be longer. The option for a no-cost extension or supplement on an existing fellowship should be easily available. Funds for childcare should be specifically considered.
4. Salary should be increased to levels commensurate with their professional status and capable of supporting a life and family if that's what's desired. Salaries that were closer to what is offered in industry would encourage a better pool of applicants and aid in leaky pipeline issues.

Proven or promising external resources or approaches

Most of my comments are inspired by working with women in the field and reading current research on what benefits their careers. For example: Kim & Moser, 2021 and Berryhill & Desrochers, 2021 and many others.

Many mentorship and training structures that are excellent exist at the graduate level but are rarely implemented at the postoc level, e.g., onboarding, cohorts, mentorship committees, career & skills development support [writing & computational skills], etc. There are many well-done and recent studies on graduate training. Applying some of those same concepts, which have worked well for graduate

students, to postdocs I think is essential going forward. Postdocs have transformed to be more than just a short steppingstone to an academic faculty position that they once were, and their presence should be defined unto themselves—not as trainees that are grouped with graduate students but as a separate group with their own unique needs, resources, and talents. The NIH has an opportunity to be a real leader for people in the postdoc position.

Response 2147

Perspectives on the postdoc roles and responsibilities

Prior to my postdoc experience—Before I began my postdoctoral training in 2015, I was fill with excitement in that this would be an extension of my Ph.D. and would involve highly specialized formal training that would not only help me evolve into an independent researcher, but to also open up many employment avenues, especially at R1 level academic institutions. I decided to pursue a postdoctoral position because of these additional profession advantages—my advisors, mentors and colleagues told me this and therefore, I had no reason to doubt them.

Post postdoctoral training experience—Toward the end (2021) and after my postdoctoral training experience there was a noticeable shift in my feelings and perspectives of what the postdoc position originally meant to me. This "career launching" experience as advertised by my mentors waned in the wake of COVID-19 pandemic. The reality set in when, during the height the pandemic, my research lab remained closed, while bars were allowed to reopen. My perception from this was that the world did not care about researchers trying to help individuals through phase 2 clinical trials and my value as researcher meant little-to-nothing to my institution. When my research lab was allowed to reopen (~ 4 months after initial lockdown) we were only allowed to operate one or two days a way over the next year that I remained in my position. Clearly, this is not the best approach to be productive to researchers who often balance several studies at a time. Unfortunately, do to lack of productivity in research, my department decided not to invest in another year and I ultimately had to try and find a position elsewhere, half way through the academic calendar.

Fundamental issues and challenges

Recruitment—One challenge inhibiting recruitment for prospective postdoctoral professionals is that there is selective institutional and advisor inbreeding. This is not new relative to today's landscape; it has been going on for decades. The quality of the postdoc therefore, becomes diminished because new research experiences are not attained, and the result is many young professionals competing for the same grants because there research acumen has not been expanded.

Retention—there seems to be a general lack of collegiality between the postdoc and the Institution. This, often times makes individuals rethink what the main important reasons as to why they chose the postdoctoral route.

Quality of Life—I chose to select a postdoctoral fellowship at a Midwestern University because the cost of living from a standardized postdoctoral salary would be cheaper in the Midwest than on the East or West coast academic institutions. Based on the current postdoctoral salaries and cost of rent in West/East coast cities, a postdoc would be spending over half of their paycheck on rent each month. This clearly can alter how an individual lives their life.

Academic Institution Budgetary restraints—Many institutions have experienced severe budget cuts as a result of pandemic-related low enrollment. This has made the prospective postdoc less affordable to many institutions where not only a competitive salary must be offered, but sufficient start up funds are needed for success. In my experiences in applying for institutions, it appears that many simply cannot afford individuals with postdoctoral training; the funds cannot meet the feasible means to conduct successful research. Further compounding this dilemma is that pandemic-related supply shortages have cause price hikes on nearly every facet of the research equipment industry.

Existing NIH policies, programs, or resources

I think the peer reviewer programs needs to have better accountability, more streamlined, and perhaps, audited in some instances where a reviewer appears to be biased and/or inexpereinced. In my own experiences and in many conversations with colleagues who submit grants at the NIH level, there appears to be considerable bias and/or differences between how reviewers review grants—there appears to be a lack of qualified reviewers who are well suited to review grants. With funding lines that run very low, many

times it takes a unanimous review of 3-5 reviewers to get funded. It appears that if you get one bad review, the chances of getting scored/funded become severely marginalized. If, for instance, a grant is submitted and 3 reviewers are scoring 8-10s and one reviewer is scoring 2-4's, there needs to be an audit on this particular reviewer and their potential history evolved around the research grant submitted. Further, if discrepancies like this exist, then their needs to be an adjunct reviewer to review the grant to determine if indeed, the reviewer was not qualified to review the grant application. One simple way to potentially avoid this issue is to have mandatory training seminars for first time grant reviewer applicants.

Proven or promising external resources or approaches

There needs to be resources (perhaps webinars) regarding realistic career pathways that may come from postdoctoral training in the year 2023 and beyond. In the past having postdoctoral experience typically meant the individual had nearly unlimited opportunities, where the individual could land a tenure track position at an R1 institution—here, the individual would be enriched in their own lab with generous start-up funds, and abundant institutional research infrastructure to facilitate their future research goals. While this is certainly possible and available today, it is to a much lesser extent. The pandemic and associated budgeting woes have limited the amount of highly regarded positions at R1 institutions that are now almost exclusively relegated to individuals not only with postdoctoral training experience but also who possess at least one career development award.

Lastly, there needs to be a revamping of resources and/or personnel readily available on how to navigate, manage, and budget the postdoc salary. Postdoctoral researchers work at a University, and not for the University. Therefore, they act as independent contractors, accruing paychecks with no taxes taken out and no retirement benefits. In my experiences as a postdoctoral scholar, there were no individuals at the University that could help me understand if taxes did indeed need to be taken out. This has been a long running controversy in the postdoctoral community where some individuals will take out taxes in good faith and precaution, whereas other do not take out taxes. What is further frustrating about this is that some of the most qualified tax professionals, CPAs, also could not give me discernable advice. This is clearly an issue that should have been resolved at the advent of when postdoc salaries where initiated.

Response 2148

Perspectives on the postdoc roles and responsibilities

I view it as the defining moments for me to positively contribute in a society by discoveries of treatments for the diseases in population.

Fundamental issues and challenges

Academic research have challenges as both postdocs and PI entered in a lab with egos. The process is slow and the salary package is not worthy enough to keep the motivations of postdoc for the research, especially in this time of inflation.

Existing NIH policies, programs, or resources

Speed up the recruitment process.

Proven or promising external resources or approaches

Improve postdoctoral recruitment and mentoring.

Response 2149

Perspectives on the postdoc roles and responsibilities

My postdoc role is really a stepping soon to becoming an independent investigator. I feel very lucky in my postdoc position since I have a lot of autonomy and freedom.I have flexibility in my schedule, and my PI is very supportive of my career and future plans, which is great.

My role includes:

1. Working on data analysis and writing manuscripts from existing data in the lab (currently 3 manuscripts are pending my analysis and writing),
2. Developing a new line of research using animal models (this includes the conception and management of the project, mentoring research assistants, and completing the animal work to collect data)—this will eventually include more wet-lab work and require data analysis and writing two manuscripts,
3. Attending trainings/conferences to learn new skills/updates in the field or present our work,
4. Submitting internal and external grants—so far, I have mostly submitted internal grants within my institution but after we collect animal data, we will be better positioned to submit a K99 (hopefully)

The expectations of me, after discussing with the PI:

Having ~7 papers in a 2-year postdoc position with 1-2 papers being bigger papers, the other manuscripts can be smaller. Am I on track to doing that? Great question! So I have submitted 2 small-ish manuscripts so far, working on the animal data will allow me to have the 2 big manuscripts by my second year of my postdoc. After receiving a training, I am able to work on one new manuscript as well, and then there will be 2 more manuscripts that I may not be able to get to honestly. In short, I think I will leave this postdoc with 4 manuscripts (if accepted for publication, which is an issue) to be realistic since I am almost halfway through with my appointment.

Fundamental issues and challenges

This is a very different position than being a PhD student. It requires adjusting to a new norm, lifestyle, expectations, freedom, and responsibility.

Pros:

1. Having autonomy and flexibility in schedule, task completion, and project selection
2. Feeling appreciated and respected as a "peer"; your PI values your input; they hired you for a reason since you have a skillset they are looking for
3. Having more opportunities to pursue training/conferences
4. General sense of relief knowing this is a "training" and you are no longer a student or pursuing a degree

Challenges:

1. Being fully responsible for a project and being expected to just know what to do is difficult and sometimes exhausting. We are not prepared to lead research efforts as PhD students, so there is this sudden expectation as a postdoc that "you know" how to do things. This should be addressed at the PhD level or early postdoc career
2. Most postdocs I have met are exhausted and overworked—the postdoc experience is very PI-specific and lab-culture-specific. I feel lucky in my position, but I can sense how other postdocs are overworked and it makes me feel like there is no support or community of postdocs since most are just exhausted: not happy enough to socialize
3. The pay is LOW! I earn $60K, $45k after tax. After paying rent, car lease and insurance, groceries, and just daily life things like parking/dental visits and health insurance costs, I am barely left with $100, if anything. This low pay makes me feel under appreciated and affects my personal life. Not having a financial safety net is a REAL stressor that impacts my productivity
4. Not having a job security. You are a postdoc for 2-3 years and that is it! No job security or future plans. The uncertainty kills productivity, combined with a low pay

Existing NIH policies, programs, or resources

I am unsure what programs exist since my funding is internal, not through NIH. I know this is a very privileged position to be in since I do not worry about funding throughout my appointment while knowing that other postdocs worry about funding on an annual basis or have to keep submitting grants to continue their work.

Postdoc demands that would increase retention and make academia a more enticing option (over industry):

1. Increase the pay—why spend 2-5 years of your life being a postdoc when any non-academic company is willing to pay you more, let you work 9-5 ONLY, and give you better benefits, better work-life balance, and better vacation days/maternity or paternity leave?
2. Make the working hours more consistent. Let us be real, we do a PhD so that we can lead a life that is not a 9-5. We appreciate our intellectual clock and work when we are inspired and productive. A life in academia offers the most flexibility and control over our schedules as long as we do not feel like we need to work overtime or weekend to meet deadlines and finish our work. So maybe reduce the work expectation so we are not in a constant state of "hustle", and make the maximum worked hours per week 40. This standardizes the expectation and forces PIs not to overwork their employees.
3. Promote transparency. Many postdocs feel that the expectations are ambiguous
4. Promote empathy and mentorship programs to improve the PIs mentorship style. Many are very toxic in academia and overwork their employees, yell at them, or belittle their achievements (yes, it happens). Having better mentors leads to better employees and an overall better mental health which leads to improved productivity. Win-win situation

Proven or promising external resources or approaches

To improve recruitment: provide financial stability, and if possible, future work contracts. We will work better if we know this position will translate to a more permanent and secure position

To improve training: improve the mentors! The PIs need to be empathetic and understanding and treat all postdocs and employees with respect and dignity. A healthy work-life balance and healthy lab culture is needed for that and this is set by the PI.

To improve working environment: set standard work hours and increase the pay

To improve mentoring: start working on this really early with MS/PhD/MD students. Good habits are formed during our initial training before we become PIs. There should be mandatory mentorship training for students and PIs to become good leaders and mentors. The academic systems are supportive of abusive mentors so long as they secure funding and publish papers, so maybe looking internally at your academic infrastructure may be a good start to dismantle this cycle of improper mentorship being celebrated as long as it yield near-sighted results (good publication for a few years then the people leave to the toxic culture and these papers will not write themselves).

To improve job satisfaction: increase pay, increase positive mentorship where people feel appreciated and praised by their mentors, give us more platforms to showcase our work as postdocs so we feel our work is impactful (which is rewarding), and create focus groups or a postdoc society where postdocs can connect and socialize together to feel valued and part of a group.

Response 2150

Perspectives on the postdoc roles and responsibilities

My perspective of postdoc positions is that they are the next step for people interested in remaining in academia and continuing on to be a professor. They are expected to perform research in a manner that is more independent than graduate students, and are expected to more actively participate in writing grants for themselves or the lab.

Fundamental issues and challenges

Postdoc positions in my field (basic science research) are overworked and underpaid. Research and academia are incredibly demanding environments were it is viewed as normal to work weeks that are closer to 50 hours than 40. On top of that, postdocs are rarely making salaries that allow them to live comfortably in metro areas. As postdocs are essentially designed to guide people towards incredibly competitive professor posts, they don't seem like a worthwhile pursuit if you are not interested in academia or if you don't feel competitive in applying for professor posts.

Existing NIH policies, programs, or resources

NIH policies could mandate increased vacation time, strict maximums on number of hours postdocs are allowed to work per week, increased salaries for postdoc positions, and other improvements that would generally make it a less grueling career path.

Proven or promising external resources or approaches

Response 2151

Perspectives on the postdoc roles and responsibilities

To me, the academic postdoc is not a useful career step unless you want to pursue an academic faculty position. And from what I have experienced during my time in graduate school, I have no interest in continuing academic research. A postdoc is just another underpaid "training" opportunity that intends to take advantage of you as cheap labor rather than help your career growth and development. Since I have already been doing that for 5 years, I do not need any more of this type of experience. I do not believe the current academic system is designed in a way that maximizes scientific integrity, progression, or training. I love and believe in science, however, I am quite discouraged by the neglect, gaslighting, and bullying I have experienced, so I will be taking my talents elsewhere. I know the postdoc is supposed to be a higher level of independence, but I have been completely independent for the last 3 years. Therefore, I do not need another academic experience on my CV, as I feel as though I have already been required to operate as a postdoc while getting paid a graduate student stipend. I think in addition to investigating postdoctoral training, the NIH should have a higher standard for predoctoral training programs (emphasis on training, not publications required) because the experiences my peers and I have had has not encouraged us to continue to contribute to scientific research in this setting. Overall, I view the postdoc as a waste of time, and I hope to receive better training in my future non-academic positions.

Fundamental issues and challenges

First and foremost, the biggest challenge is the postdoc salary. Academic research pretends it does not exist in a capitalist society (and shames their underpaid graduate students and postdocs for wanting higher pay). However, the reality is that America is a capitalist society, inflation is at an all-time high, and the pay from the NIH is not keeping pace with this. It is an extreme privilege to make a salary that is barely above the cost of living (especially since all the "premier" research institutions are in the most expensive cities) when you are a highly capable professional with a Ph.D. (and have been an underpaid graduate student for 5-6 years). It is even more of a privilege to be expected to be in this position for ~5 years with no promotions or raises. And to be told that in exchange for this low salary, you'll be receiving "training" is an absolute joke. If you would like to retain people, you would need to pay them more and provide a higher level of training (rather than use their higher level of independence as an excuse to provide less training). It is quite obvious from the graduate student level that there is no clear standard of training, so it is a hard sell that postdocs are receiving some kind of great training that makes this underpaid position worth it.

Existing NIH policies, programs, or resources

There needs to be a system in which trainees are guaranteed training and there should be repercussions for PIs not providing training. Currently, trainees are at the mercy of the PIs who can say whatever they want and then do whatever they want (i.e. say you will receive training but not provide it because they are really just using trainees as cheap labor for their own lab and reputation). There needs to be standards of training that everyone is guaranteed as well as negative consequences for those not following the guidelines (make it a requirement that every trainee has an IDP? Have a place for trainees to report lack of training?). Overall, not very impressed by this unchecked system of power.

Proven or promising external resources or approaches

No response

Response 2152

Perspectives on the postdoc roles and responsibilities

I view postdocs as a dedicated stepping stone that is considered necessary for future academic positions. This is an opportunity to develop new research areas and diversify your research experience.

Fundamental issues and challenges

There is no guarantee of full-time work after postdocs are completed. Postdocs are underpaid and overworked. This is not a problem that is unique to postdoctoral scientists by any means. But if NIH is interested in improving retention, they need to propose mechanisms that make the positions more attractive and permanent.

Existing NIH policies, programs, or resources

Modify to include longer-term fellowships that allowed preliminary transitions into full-time positions at universities.

Proven or promising external resources or approaches

Consider "bridge to faculty" fellowships offered by some universities like University of Illinois Chicago or University of South Carolina

Response 2153

Perspectives on the postdoc roles and responsibilities

The postdoc position is an advanced training position that is fundamental to preparing individuals for a career as an independent scientist, particularly in an academic setting. The postdoc position should be one where individuals with a PhD can further develop their skills in independently driving projects and in how to engage critically with other scientists about their work.

Fundamental issues and challenges

Most institutions offer minimal vacation time to postdocs, and some institutions don't offer paid parental leave or are just beginning to do so, making postdocs feel somewhat trapped in the job. Furthermore, academic faculty positions are hard to come by and can be even harder to come by if individuals cannot just pick up and move anywhere. A number of industry positions do not require postdoc experience, come with better financial compensation, and better personal leave policies, making them ultimately more attractive, whether from the outset or during the postdoc tenure. Retention is difficult when better compensation on multiple fronts is available elsewhere and the primary goal of an academic postdoc position seems particularly difficult to obtain.

Existing NIH policies, programs, or resources

The NIH has a policy on how much postdocs should make based on their experience level for individuals on training grants and individual fellowships, and they could do more to actually enforce that institutions follow this policy for training grants, and they could expand this policy to include all postdocs paid through NIH grant funding so that there is better enforcement of postdocs actually being compensated based on their experience level. I know of postdocs who are multiple years into their postdoc (4+) that don't even make the minimum for a Year 0 postdoc on a training grant or fellowship. There should be more pressure on institutions to compensate postdocs according to their experience so that postdocs are at least given somewhat reasonable financial compensation (albeit at lower levels than could be obtained outside of the academic setting, which still poses problems for retention). Since academic postdoc positions already pay less than industry positions aimed at individuals with the same level of experience, there should at least be more pressure for academic postdocs to be more fairly compensated if retention of individuals in academic careers is desired.

Proven or promising external resources or approaches

No response

Response 2154

Perspectives on the postdoc roles and responsibilities

Postdoctoral training is meant to facilitate transition into an independent position. It can be used to learn new cutting-edge techniques and help build a portfolio to aid in that transition process. Although contributing to the PI's research is key, the role of the PI in fostering independence is more important.

Fundamental issues and challenges

Salary caps set by the NIH currently do not account for rising costs. The huge disparity in pay between industry (entry level) and postdoc positions limits recruitment and retention of postdocs looking to explore options after their PhD.

Existing NIH policies, programs, or resources

The pathway to independence award needs to be better tailored to accommodate subject switches. The language in the FOA needs to be clear as to when exactly a postdoc is eligible to apply. This award has to be submitted in the third year of your postdoc but one of the criteria that candidates are judged on is productivity (visible: papers); which can be difficult to demonstrate within 3 years especially if candidates change fields.

Proven or promising external resources or approaches

No response

Response 2155

Perspectives on the postdoc roles and responsibilities

I am in a clinical and research role as a clinical health psychology postdoctoral fellow. I have 40% research time, 50% clinical time and 10% didactics.

Fundamental issues and challenges

My QOL has been the lowest during my fellowship year than any other year of training—including internship year when I was defending my dissertation and working 60-70 hours/week. It has been so low because I feel like I am over-supervised and under-supported, I still have no power but I am held to a high degree of responsibility, and I have a doctorate and am making 50k, when my friends and peers who chose not to do a fellowship are making 2-5x this year what I am making. 50k in a busy city is not nearly enough to not face very significant financial stress. I can choose between living in the city or being able to afford going out to eat, but not both. The financial stress hurts worse when I feel like the pay cut I took for the education didn't actually provide the education or mentorship I thought I would have. I have several peers (in multiple different fields) who have quit their postdocs, and I understand it completely. We have great support from our postdoc director, but he has so little power and isn't involved in my day-to-day life at all. It feels really difficult as well, because emails are sent and responded to on the weekend and as late as 9 or 10pm at night. Add to that only getting ten days of PTO total—of course I am burnt out. Anyone would be burnt out in my shoes. And my career hasn't really even started, but in my first ever professional role, I am just barely hanging on and miserable.

Existing NIH policies, programs, or resources

- Expanding mental health resources (my academic insurance somehow doesn't cover therapy, even though I am a mental health provider myself)
- Affinity groups for minoritized folks (I am LGBTQ+, but I think this would benefit BIPOC folks as well, or parents, etc)
- More PTO—10 days total is inhumane
- Higher salaries, especially in big cities. A nationwide minimum is a good start, but for me in a huge metropolis, it barely makes a dent, when the folks in Lawrence, KS, are probably living just fine off 50K
- Clear reporting lines for ethical violations of supervisors, ideally with the option too be anonymous
- Allow us the option to charge for working overtime, or create another pathway where we get paid for all the work we do outside of the 40hrs/week we are on currently paid for

Proven or promising external resources or approaches

- Affinity mentorship—I would have loved to have a mentor who was also queer and/or a woman
- Mental health or other non-sick days; we are only allowed to take sick leave when we are sick, but the amount of sick leave we get is equal to our total PTO.shouldn't I be able to take a sick day for a necessary doctors appointment or for therapy? And yet, these requests were denied because I can't take sick "ahead of time"—this creates a culture where lying is rewarded and honest people are burnt out to a crisp. Sick days should be health days and we should be able to spend them in therapy or getting our physical therapy or taking our kid to his neurologist if we need to

Response 2156

Perspectives on the postdoc roles and responsibilities

Postdocs are a mainstay of my lab and account for most of my lab's research productivity. I view them as employees not as trainees.

Fundamental issues and challenges

Since the onset of COVID, postdocs have essentially disapeared in the US. This is driven by low pay and the tenousiousness of their appointments.

Existing NIH policies, programs, or resources

Pay them adquately and understand that is taking them longer to achieve independence.

Proven or promising external resources or approaches

No response

Response 2157

Perspectives on the postdoc roles and responsibilities

The postdoc is key career development position where the trainee is till very much building research skills, communication skills, critical thinking skills, and establishing a higher level of independence as a scientist. Postdocs are essential for the success of the biomedical research field both in terms of its present workforce and its future workforce, both in academia and industry

Fundamental issues and challenges

Postdoc stipends are too low to be attractive given that many postdocs are also worried about not finding a stable, good paying job after completing postdoctoral training. The NIH needs to not only increase what it pays postdocs via NRSA F32 and T32 but also dramatically increase the amount of the average R01 award to at least $350-400k direct/year and also raise R01 paylines to a~20-25% to allow all postdocs to be paid better and also allow for more the funding of more stable, senior research staff positions that postdocs can transition into. Many postdocs do not want to become faculty/PIs or work in industry and would be happy staying on as senior research staff scientist in academia if the pay was competitive and

some level of job security existed. They feel that other paths into academia via the faculty track are too risky and more based on luck than hard work because the number of faculty jobs is too small and highly competitive. Thus, they feel that they might as well just jump into an industry job or leave research science altogether after PhD based on short-term financial benefits rather than spending more years in training that they equate with buying a lottery ticket.

Existing NIH policies, programs, or resources

Increase the NIH budget to increase not only NIH R01 paylines/number of R01s but also average R01 award amounts. Nothing else matter that much is postdocs don't see a future with stable, gainful employment as research scientist. They feel that other paths into academia via the faculty track are too risky and more based on luck than hard work because the number of faculty jobs is too small and highly competitive.hus, they feel that they might as well just jump into an industry job or leave research science altogether after PhD based on short-term financial benefits rather than spending more years in training that they equate with buying a lottery ticket.
